ABSTRACT

A New $z$ - Domain Continued Fraction Expansion and its Use in the Generation of Stable Transfer Functions

Ling Luo

A new $z$ - domain continued fraction expansion ($CFE$) has been proposed. It is shown that the ratio of an anti-mirror - image polynomial to a mirror - image polynomial originating from the denominator of a transfer function can be expanded into this new type of $z$ - domain $CFE$. Unlike the earlier types of $z$ - domain continued fraction expansions, this new type is not unique for a given polynomial, and there will be a large number of possibilities. Algorithms have been proposed to obtain the various possible $CFEs$, which are implemented using MATLAB software. For the denominators of some well - known filters like Butterworth lowpass filters, Butterworth lowpass Complementary Pole-pair Filters ($CPPF$) and Chebyshev lowpass filters, the required coefficients of the $CFEs$ are obtained. Also, starting from the coefficients of the $CFEs$, algorithms have been presented to generate stable transfer functions for filters such as lowpass, highpass and bandpass in the $z$ - domain.
ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to my thesis supervisor, Dr. Venkat Ramachandran, for his valuable guidance throughout the course of this thesis, for his extremely careful, critical and thorough review of my work. He introduced me to this exciting area of filters and was a constant source of inspiration. I also would like to thank the examiners Dr. C.S. Gargour and Dr. Weiping Zhu for their helpful comments in the final preparation of the thesis.

Chapter 1

Introduction

1.1 General

The design of any filter requires that the resulting transfer function be stable. In $1 - D$ discrete domain, it is required that the denominator polynomial shall contain its roots within the unit circle. For a $1 - D$ IIR filter (Infinite-duration Impulse Response), a transfer function is given by

$$H(z) = \frac{N(z)}{D(z)} = \frac{p_0 + p_1 z^{-1} + p_2 z^{-2} + \ldots + p_M z^{-M}}{d_0 + d_1 z^{-1} + d_2 z^{-2} + \ldots + d_N z^{-N}}$$ (1.1)

which can be put in factored forms as:

$$H(z) = \frac{p_0}{d_0} \prod_{k=1}^{M} (1 - \xi_k z^{-1}) \prod_{k=1}^{N} (1 - \lambda_k z^{-1})$$ (1.2)

$$= \frac{p_0}{d_0} z^{(N-M)} \prod_{k=1}^{M} (z - \xi_k) \prod_{k=1}^{N} (z - \lambda_k)$$ (1.3)

where $\xi_1, \xi_2, \ldots, \xi_M$ are the finite zeros of $H(z)$, and $\lambda_1, \lambda_2, \ldots, \lambda_N$ are the finite poles of $H(z)$. For a causal IIR filter, the ROC (Region of Convergence, the set of values of $z$ for which the $z$-transform converges) of the transfer function $H(z)$ is thus
exterior to the unit circle going through the pole furthest from the origin, the ROC is given by

\[ |z| > \max_k |\lambda_k| \]

It implies that all poles of a stable and causal transfer function \( H(z) \) must be strictly inside the unit circle. It means the zeros of \( D(z) \) shall be contained within the unit circle.

If the transfer function is available in the factored forms as shown in [1], it is relatively easy to determine, whether it is stable or not.

However, when a digital filter is implemented, it is highly preferable that alternative conditions are desired so that one doesn’t have to obtain the transfer function and then determine its stability. Also, when the denominator of the transfer function is not given in the factored forms, tests can be carried out, like Jury-Marden Stability Criterion [1], in order to determine the stability of the filter.

1.2 Mirror-image and Anti-mirror-image Polynomials and Some Important Properties

The authors of [2], [3] and [4] have established several useful properties of a stable polynomial \( D(z) \) having all its roots inside the unit circle in the \( z \)-plane. Some of those properties are discussed below[2]. Let,

\[ D(z) = a_n z^n + a_{n-1} z^{n-1} + \ldots + a_1 z + a_0 = \sum_{i=0}^{n} a_i z^i \quad (1.4) \]

with \( a_n \) is positive. \( D(z) \) can be decomposed as the sum of mirror-image polynomial

\[ F_1(z) = \frac{[D(z) + z^n D(z^{-1})]}{2} \quad (1.5) \]
and the anti-mirror-image polynomial

\[ F_2(z) = \frac{[D(z) - z^n D(z^{-1})]}{2} \] \hspace{1cm} (1.6)

For \( D(z) \) which has its zeros inside the unit circle, the necessary and sufficient conditions are [2],
(a) the zeros of \( F_1(z) \) and \( F_2(z) \) are located on the unit circle,
(b) they are simple,
(c) they separate each other and
(d) \( |a_{2n}| < 1 \), [4]

In this paper, we affix the subscript "e" for all polynomials and functions when the order \( n \) is even, and the subscript 'o' when \( n \) is odd. Thus, \( F_1(z) \) and \( F_2(z) \) should be represented by \( F_{1e}(z) \) and \( F_{2e}(z) \) respectively when \( n \) is even; and by \( F_{1o}(z) \) and \( F_{2o}(o) \) respectively when \( n \) is odd.

It is also necessary to ensure that [1]
(a) \( D(1) > 0 \), and
(b) \( (-1)^n D(-1) > 0 \)
these are necessary conditions for the zeros of \( D(z) \) to be contained within the unit circle.

Some properties of the mirror-image and the anti-mirror-image polynomials are discussed below [5].

**Result 1** If \( D(z) \) contains a factor \( d_1(z) = z^2 + a_1 z + 1 \), \( 0 \leq |a_1| < 2 \), then both \( F_1(z) \) and \( F_2(z) \) also contain \( d_1(z) \).

**Result 2** \( (z + 1) \) is a factor of both \( F_{2e}(z) \) and \( F_{1o}(z) \).

**Result 3** \( (z - 1) \) is a factor of both \( F_{2e}(z) \) and \( F_{2o}(z) \).

From Schussler's theorem and Results 1, 2 and 3, it is concluded:
(a) All the zeros of $F_{1e}$ are complex conjugate pairs and lie on the unit circle.

(b) A zero of $F_{1o}$ is -1, other zeros are complex conjugate pairs and lie on the unit circle.

(c) $\pm 1$ are zeros of $F_{2e}$, other zeros are complex conjugate pairs and lie on the unit circle.

(d) A zero of $F_{2o}$ is 1, other zeros are complex conjugate pairs and lie on the unit circle.

Therefore, these polynomials can be expressed as follows.

**Table 1.1: Expansions of $F_1(z)$ and $F_2(z)$** [5]

| $n$ even | $F_{1e} = k_{1e} \prod_{i=1}^{n/2} (z^2 + a_i z + 1), 0 \leq |a_i| < 2$ |
|----------|------------------------------------------------------------------|
|          | $F_{2e} = (z^2 - 1)k_{2e} \prod_{i=1}^{(n-2)/2} (z^2 + \beta_i z + 1), 0 \leq |\beta_i| < 2$ |
| $n$ odd  | $F_{1o} = (z + 1)k_{1o} \prod_{i=1}^{(n-1)/2} (z^2 + \gamma_i z + 1), 0 \leq |\gamma_i| < 2$ |
|          | $F_{2o} = (z - 1)k_{2o} \prod_{i=1}^{(n-1)/2} (z^2 + \delta_i z + 1), 0 \leq |\delta_i| < 2$ |

where $k_{1e}$, $k_{2e}$, $k_{2o}$ and $k_{2o}$ are real and positive constants.

### 1.3 Known Continued Fraction Expansions [3][6]

Based on the above properties, certain continued fraction expansions exist, which are discussed below:

The types of $CFEs$ are:
1) CFE1:
When $n$ is even or odd,

$$\frac{F_1(z)}{F_2(z)} = ka(1)\frac{(z + 1)}{(z - 1)} + \frac{1}{ka(2)\frac{(z + 1)}{(z - 1)} + \frac{1}{ka(3)\frac{(z + 1)}{(z - 1)} + \ldots}} \quad (1.7)$$

where $ka(1), ka(2)\ldots ka(n)$ are real and positive.

2) CFE2:
(a) CFE 2a :
For $n$ is even,

$$\frac{F_{1e}(z)}{F_{2e}(z)} = kb(1)\frac{(z - 1)}{(z + 1)} + \frac{1}{kb(2)\frac{(z - 1)}{(z + 1)} + \frac{1}{kb(3)\frac{(z - 1)}{(z + 1)} + \ldots}} \quad (1.8)$$

where $kb(1), kb(2)\ldots kb(n)$ are real and positive.

(b) CFE 2b :
or if $n$ is odd,

$$\frac{F_{2o}(z)}{F_{1o}(z)} = kb(1)\frac{(z - 1)}{(z + 1)} + \frac{1}{kb(2)\frac{(z - 1)}{(z + 1)} + \frac{1}{kb(3)\frac{(z - 1)}{(z + 1)} + \ldots}} \quad (1.9)$$

where $kb(1), kb(2)\ldots kb(n)$ are real and positive.

3) CFE 1a
In addition to the above set of continued fraction expansions, there exist other forms, one of them ( we call this as CFE 1a ) is obtained by reformulating the mirror - image and anti - mirror - image polynomials, and they are briefly discussed below [7]:

If the degree is even,

$$F_1(z) = \frac{zD(z) + z^nD(z^{-1})}{z + 1} \quad (1.10)$$
and

\[ F_2(z) = \frac{D(z) - z^n D(z^{-1})}{\overline{z + 1}} \]  \hspace{1cm} (1.11)

If the degree is odd,

\[ F_1(z) = \frac{D(z) + z^n D(z^{-1})}{\overline{z + 1}} \]  \hspace{1cm} (1.12)

and

\[ F_2(z) = \frac{zD(z) - z^n D(z^{-1})}{\overline{z + 1}} \]  \hspace{1cm} (1.13)

The CFE 1a is obtained as

\[ n = \text{even} \]

\[ \frac{F_1(z)}{F_2(z)} = r_1(z - 1) + \frac{1}{r_2(1 - z^{-1}) + \frac{1}{r_3(z-1) + \frac{1}{r_4(z-1) + \cdots}}} \]  \hspace{1cm} (1.14)

\[ n = \text{odd} \]

\[ \frac{F_2(z)}{F_1(z)} = r_1(z - 1) + \frac{1}{r_2(1 - z^{-1}) + \frac{1}{r_3(z-1) + \frac{1}{r_4(z-1) + \cdots}}} \]  \hspace{1cm} (1.15)

where the coefficients \( r' \)'s are positive. It must be noted that the positivity of \( r' \)'s will not be sufficient to prove that \( D(z) \) contains all its zeros within the unit circle[8] and [9]. In [8], there are alternative forms of CFE's based on the decompositions given in Eqs (1.10), (1.11) and Eqs (1.12), (1.13). They are not considered in this thesis, because the positiveness of the coefficients does not guarantee stability of the transfer function generated by these CFEs.

4) CFE3

It has been recently reported that another type of continued fraction expansion is possible, as given below [6].
For $n$ is odd,

\[ CFE \, 3a \]

\[
\frac{F_{1o}(z)}{F_{2o}(z)} = k_z(1)\frac{z+1}{z-1} + \frac{1}{k_f(2)\frac{z-1}{z+1} + k_z(2)\frac{z+1}{z-1} + \ldots.} \tag{1.16}
\]

For $n$ is even,

\[ CFE \, 3b \]

\[
\frac{F_{1e}(z)}{F_{2e}(z)} = k_f(1)\frac{z-1}{z+1} + k_z(1)\frac{z+1}{z-1} + \frac{1}{k_f(2)\frac{z-1}{z+1} + k_z(2)\frac{z+1}{z-1} + \ldots.} \tag{1.17}
\]

1.4 Scope of the thesis

It is known that, for a stable $1 - D$ IIR filter, the denominator of the transfer function, whose zeros lie inside the unit circle, can be decomposed as the mirror-image polynomial $F_1(z)$ and the anti-mirror-image polynomial $F_2(z)$. In addition, the function $\frac{F_1(z)}{F_2(z)}$ or its reciprocal has simple poles and zeros on the unit circle, and they interlace. The methods to generate continued fraction expansions from mirror-image polynomials $F_1(z)$ and the anti-mirror-image polynomials $F_2(z)$ are discussed in following chapters.

One of the objectives of this thesis is to expand the denominator of a stable transfer function into $CFEs$.

Chapter 1 provides an overview of the stability of the IIR filter, mirror-image polynomial, anti-mirror-image polynomial and some properties; it also presents an introduction to the field of the known $CFE1$, $CFE2$ and $CFE3$. In Chapter 2, the methods to generate the coefficients of continued fraction expansions are described, which are illustrated with MATLAB. Chapter 2 is concerned primarily with the new expansion type of $CFE4$, which is given below:
CFE4:

For \( n = \text{odd} \),
\[
\frac{F_{2n}(z)}{F_{1n}(z)} = kc(0)\left(\frac{z-1}{z+1}\right) + kc(1)\left(\frac{z^2-1}{z^2+\gamma_1 z+1}\right) + \frac{1}{kc(2)\left(\frac{z^2-1}{z^2+\gamma_2 z+1}\right) + \frac{1}{kc(3)\left(\frac{z^2-1}{z^2+\gamma_3 z+1}\right) + \cdots}}
\]
where \( kc(0), kc(1), kc(2) \ldots kc\left(\frac{n-1}{2}\right) \) are real and positive; \( 0 \leq |\gamma_i| < 2, i = 1, 2 \ldots \frac{n-1}{2} \).

For \( n = \text{even} \),
\[
\frac{F_{2n}(z)}{F_{1n}(z)} = kc(1)\left(\frac{z^2-1}{z^2+\gamma_1 z+1}\right) + \frac{1}{kc(2)\left(\frac{z^2-1}{z^2+\gamma_2 z+1}\right) + \frac{1}{kc(3)\left(\frac{z^2-1}{z^2+\gamma_3 z+1}\right) + \cdots}}
\]
where \( kc(0) = 0; kc(1), kc(2) \ldots kc\left(\frac{n}{2}\right) \) are real and positive; \( 0 \leq |\gamma_i| < 2, i = 1, 2 \ldots \frac{n}{2} \).

In addition, algorithms have been given to obtain the various coefficients of CFE4.

In Chapter 3, Chapter 4 and Chapter 5, a few applications are outlined. The most common types of filters, namely Butterworth lowpass filters, Butterworth lowpass CPPF (Complementary Pole-pair Filter) and Chebyshev lowpass filter, have been considered in detail with respect to the above mentioned theories. Chapter 3 establishes algorithms to produce the coefficients \( ka, kb, kc \) and \( \gamma \) of the continued fraction expansions (CFEs) using the concept of mirror-image polynomial and anti-mirror-image polynomial for Butterworth lowpass filters and Butterworth CPPFs lowpass filters in \( z \) domain after bilinear transformation.

Chapter 4 is devoted to an algorithm which produces the coefficients \( ka, kb, kc \) and \( \gamma \) of the continued fraction expansion (CFEs) using the concept of mirror-image polynomial and anti-mirror-image polynomial for Chebyshev lowpass filters in \( z \) domain after bilinear transformation.

Another objective of this thesis is to produce stable lowpass filter transfer functions from coefficients \( kc \) and \( \gamma \) of continued fraction expansion (CFE4). To produce highpass and bandpass filters in \( z \) domain, first, highpass and bandpass filters in \( s \) domain are characterized; then, using bilinear transformation, the transfer
functions in \( z \) domain are obtained, and are discussed in Chapter 5.

This thesis can be considered as a starting point for application of continued fraction expansions in filter design. The same methods can be considered as suggestions for any other stable filter designs.
Chapter 2

The New Type of Continued Fraction Expansion and the Determination of its Coefficients

First, we review some of the issues associated with CFE1, CFE2 and CFE3 techniques; then we produce a new type of CFE4. The sufficient and necessary condition are that the denominator of a stable IIR filter can be decomposed as the mirror-image polynomial $F_1(z)$ and the anti-mirror-image polynomial $F_2(z)$, and $\frac{F_1(z)}{F_2(z)}$ can be expressed as continued fraction expansions of CFE1, CFE2, CFE3 and CFE4, where all coefficients of the continued fraction expansions are real and positive.

Secondly, the methods of coefficient determination for four kinds of continued fraction expansions are introduced.

Finally, there are programmes on the computer by using MATLAB to obtain the various coefficients.
2.1 The new type of $z$ - domain $CFE$

We now introduce the new type of continued fraction expansion given as follows:

*CFE 4a:* For $n$ odd,

$$\frac{F_{2n}(z)}{F_{1n}(z)} = kc(0)\frac{(z - 1)}{(z + 1)} + kc(1)\frac{(z^2 - 1)}{(z^2 + \gamma_1 z + 1)} + \frac{1}{kc(2)\frac{(z^2 - 1)}{(z^2 + \gamma_2 z + 1)} + \frac{1}{kc(3)\frac{(z^2 - 1)}{(z^2 + \gamma_3 z + 1)} + \ldots \ldots}} (2.1)$$

*CFE 4b:* For $n$ even,

$$\frac{F_{2n}(z)}{F_{1e}(z)} = kc(1)\frac{(z^2 - 1)}{(z^2 + \gamma_1 z + 1)} + \frac{1}{kc(2)\frac{(z^2 - 1)}{(z^2 + \gamma_2 z + 1)} + \frac{1}{kc(3)\frac{(z^2 - 1)}{(z^2 + \gamma_3 z + 1)} + \ldots \ldots}} (2.2)$$

We shall now prove the existence of $CFE 4a$.

Since $n$ is odd, there exists a zero of $F_{1n}(z)$ at $z = -1$, we can write

$$\frac{F_{2n}(z)}{F_{10}(z)} = kc(0)\frac{(z - 1)}{(z + 1)} + \phi_1(z) (2.3)$$

where $\phi_1(z)$ is of the type $\frac{F_{2n}(z)}{F_{1e}(z)}$; the degree of $\phi_1(z)$ is one less than that of $\frac{F_{2n}(z)}{F_{10}(z)}$ and is of even order now.

It is known from [3] that $kc(0)$ is real and positive.

$\phi_1(z)$ can now be written as

$$\phi_1(z) = kc(1)\frac{z^2 - 1}{z^2 + \gamma_1 z + 1} + \phi_2(z) (2.4)$$

This is possible, because $\phi_1(z)$ contains its poles and zeros located on the unit circle which are simple and interlacing [5], which means that $|\gamma_1| < 2$.

It is known that $kc(1)$ is real and positive [10]; also $\phi_2(z)$ is of similar form as $\phi_1(z)$. $\phi_2(z)$ contains poles and zeros on the unit circle which are simple and
interlace. One of the poles of \( \frac{1}{\phi_2(z)} \) is chosen and then expanded further. Therefore, \( \frac{1}{\phi_2(z)} \) can now be expanded similar to the one given in Equ (2.4), and the process can be continued. This shows that \( CFE \ 4a \) given by Equ (2.1) and \( CFE \ 4b \) given by Equ (2.2) are always possible.

The steps for the process will be as follows:

(i) Starting from the given \( D(z) \), formulate the mirror - image polynomial \( F_1(z) \) as given by Eqs (1.5) and the anti - mirror - image polynomial \( F_2(z) \) as given by Eqs (1.6).

(ii) Select one pair of roots on the unit circle from \( F_1(z) \) and expand \( \frac{F_2(z)}{F_1(z)} \) into \( CFE \ 4a \) or \( CFE \ 4b \), as the case maybe.

The following observations can be made:

(i) If the order of \( D(z) \) is even, we start with the ratio \( \frac{F_{2e}(z)}{F_{1e}(z)} \). The coefficient \( kc(0) \) corresponding to the term \( \frac{z-1}{z+1} \) doesn’t need be taken out first. The same can be obtained in \( CFE \ 4b \) at any step during the expansion.

(ii) One can choose any of the zeros of \( F_{1e}(z) \) or \( F_{1o}(z) \) to start with. In fact, the same is possible at every step in \( CFE \ 4a \) or \( CFE \ 4b \). Therefore, a large number of \( CFE’s \) of this type will be possible. This is in sharp contract to the existence of \( CFE1 \), \( CFE2 \) and \( CFE3 \), which are unique.

### 2.2 Determination of the Coefficients of the Continued Fraction Expansion

1) \( CFE1 \):

For \( n \) even or odd,

\[
\frac{F_1(z)}{F_2(z)} = ka(1)\frac{(z+1)}{(z-1)} + \frac{1}{\frac{F_1(z)}{F_2(z)}} \tag{2.5}
\]
\[ \lim_{z \to 1} \frac{z - 1}{z + 1} \frac{F_1(z)}{F_2(z)} \bigg|_{z=1} = ka(1) \]

The above procedure is recursive, so,

\[ \frac{F_3'(z)}{F_4'(z)} = ka(2) \frac{(z + 1)}{(z - 1)} + \frac{1}{\frac{F_3(z)}{F_4(z)}} \]

Using the same procedure, we can obtain \( ka(1), ka(2), ka(3) \ldots ka(n) \), where \( n \) is the degree of mirror-image polynomial or anti-mirror polynomial.

2)

(a) CFE 2a:

For \( n \) even,

\[ \frac{F_{1e}(z)}{F_{2e}(z)} = kb(1) \frac{(z - 1)}{(z + 1)} + \frac{1}{\frac{F_3(z)}{F_4(z)}} \]

\[ kb(1) = \lim_{z \to -1} \frac{z + 1}{z - 1} \frac{F_{1e}(z)}{F_{2e}(z)} \bigg|_{z=-1} \]

The above procedure is recursive, so,

\[ \frac{F_3'(z)}{F_4'(z)} = kb(2) \frac{(z - 1)}{(z + 1)} + \frac{1}{\frac{F_3(z)}{F_4(z)}} \]

Using the same procedure, we can obtain \( kb(1), kb(2), kb(3) \ldots kb(n) \), where \( n \) is the degree of mirror-image polynomial or anti-mirror polynomial.

(b) CFE 2b:

For \( n \) odd,

\[ \frac{F_{2o}(z)}{F_{1o}(z)} = kb(1) \frac{(z - 1)}{(z + 1)} + \frac{1}{\frac{F_3(z)}{F_4(z)}} \]

13
\[ kb(1) = \lim_{z \to -1} \frac{z + 1 F_{20}(z)}{z - 1 F_{10}(z)} \mid_{z=-1} \quad (2.12) \]

The above procedure is recursive, so,

\[ \frac{F'_4(z)}{F'_3(z)} = kb(2) \frac{(z - 1)}{(z + 1)} + \frac{1}{F'_3(z)} \frac{F'_3(z)}{F'_3(z)} \quad (2.13) \]

Using the same procedure, we can obtain \( kb(1), kb(2), kb(3) \ldots kb(n) \), where \( n \) is the degree of mirror-image polynomial or anti-mirror polynomial.

3)

(a) \( CFE \ 3a \):

For \( n \) is odd,

\[ kz(1) = \lim_{z \to -1} \frac{z - 1 F_{10}(z)}{z + 1 F_{20}(z)} \mid_{z=1} \quad (2.14) \]

where \( kf(1) = 0 \).

(b) \( CFE \ 3b \):

For \( n \) is even,

\[ kf(1) = \lim_{z \to -1} \frac{z + 1 F_{1e}(z)}{z - 1 F_{2e}(z)} \mid_{z=-1} \quad (2.15) \]

\[ kz(1) = \lim_{z \to 1} \frac{z - 1 F_{1e}(z)}{z + 1 F_{2e}(z)} \mid_{z=1} \quad (2.16) \]
4)
(a) \( CFE \ 4a \):

For \( n \) odd,

\[
\frac{F_{2n}(z)}{F_{1n}(z)} = kc(0) \frac{(z - 1)}{(z + 1)} + \frac{\frac{F'_{2n}(z)}{F'_{1n}(z)}}{\frac{F'_{2n}(z)}{F'_{1n}(z)}}
\]  

(2.17)

\[
kc(0) = \lim_{z \to -1} \frac{z + 1 F_{2n}(z)}{z - 1 F_{1n}(z)} \bigg|_{z=-1}
\]

(2.18)

Then, the degrees of \( F'_{1n}(z) \) and \( F'_{2n}(z) \) are even.

\[
\frac{F'_{2n}(z)}{F'_{1n}(z)} = kc(1) \frac{(z^2 - 1)}{(z^2 + \gamma_1 z + 1)} + \frac{1}{\frac{F'_{2n}(z)}{F'_{1n}(z)}}
\]  

(2.19)

\[
kc(1) = \lim_{z \to \text{root}} \frac{z^2 + \gamma_1 z + 1 F'_{2n}(z)}{z^2 - 1 F'_{1n}(z)} \bigg|_{z=z_1}
\]

(2.20)

\( z_1 \) is one of the pair of roots of complex conjugate for \( z^2 + \gamma_1 z + 1 \).

Using the same procedure, we can obtain \( kc(0), kc(1), kc(2) ... kc(\frac{n-1}{2}) \), where \( n \) is the degree of mirror-image polynomial or anti-mirror polynomial.

(b) \( CFE \ 4b \):

For \( n \) even,

\( kc(0) = 0 \).

The remaining coefficients are obtained as in Eqs (2.19) and (2.20).

Remark:

The foregoing algorithm describes a way of obtaining \( kc \) and \( \gamma \) coefficients of a continued fraction expansion. However, for \( CFE4 \), as the degree of mirror-image polynomial and anti-mirror-image polynomial increases, the number of different terms in \( kc(1), kc(2) \) ... and \( \gamma(1), \gamma(2) \) ... increases correspondingly. \( kc(1), \)
\(kc(2)\) and \(\gamma(1), \gamma(2)\) are different values when we change the order of selecting subpolynomials of \(F_{1e}(z)\) or \(F'_{1e}(z)\), \(F_{3e}(z)\) or \(F'_{3e}(z)\), \(F_{5e}(z)\) or \(F'_{5e}(z)\) as the denominators \(z^2 + \gamma_i z + 1\) of the continued fraction expansion, \(i = 1, 2, 3, \ldots \frac{n}{2}, n = \text{even}\) or \(i = 1, 2, 3, \ldots \frac{n-1}{2}, n = \text{odd}\).

We know that \(F_1(z)\) and \(F_2(z)\) can be expressed as:

\[
F_{1e} = k_{1e} \prod_{i=1}^{n/2} (z^2 + a_i z + 1), 0 \leq |a_i| < 2
\]  
(2.21)

\[
F_{2e} = (z^2 - 1)k_{2e} \prod_{i=1}^{(n-2)/2} (z^2 + \beta_i z + 1), 0 \leq |\beta_i| < 2
\]  
(2.22)

\[
F_{1o} = (z + 1)k_{1o} \prod_{i=1}^{(n-1)/2} (z^2 + \gamma_i z + 1), 0 \leq |\gamma_i| < 2
\]  
(2.23)

\[
F_{2o} = (z - 1)k_{2o} \prod_{i=1}^{(n-1)/2} (z^2 + \delta_i z + 1), 0 \leq |\delta_i| < 2
\]  
(2.24)

Where \(k_{1e}, k_{2e}, k_{1o}\) and \(k_{2o}\) are positive constants.

\(kc(1), kc(2)\) and \(\gamma(1), \gamma(2)\) in different groups are determined when we change the order of selecting subpolynomials of \(F_{1e}(z)\) or \(F'_{1e}(z)\), \(F_{3e}(z)\) or \(F'_{3e}(z)\), \(F_{5e}(z)\) or \(F'_{5e}(z)\) as the denominators \(z^2 + \gamma_i z + 1\) of the continued fraction expansion, which is illustrated by an example as follows, assuming \(n = 6\).
2.2.1 Example

\[ F_{1e} = (z^2 + a_1z + 1)(z^2 + a_2z + 1)(z^2 + a_3z + 1), \quad 0 \leq |a_i| < 2 \]

1) step 1, we first select \( \gamma_1 = \alpha_1 \), for \( kc(1) \),

\[ \frac{F_{3e}(z)}{F_{1e}(z)} = kc(1) \frac{(z^2 - 1)}{\left(\frac{z^2 + \alpha_1 z + 1}{z^2 + \zeta_1 z + 1}\right)} + \frac{1}{F_{3e}(z)} \]

then, \( F_{3e}(z) = (z^2 + \zeta_1 z + 1)(z^2 + \zeta_2 z + 1), \quad 0 \leq |\zeta_i| < 2, \)

step 2, we select \( \gamma_2 = \zeta_1 \), for \( kc(2) \),

\[ \frac{F_{5e}(z)}{F_{1e}(z)} = kc(1) \frac{(z^2 - 1)}{\left(\frac{z^2 + \alpha_1 z + 1}{z^2 + \zeta_1 z + 1}\right)} + \frac{1}{F_{3e}(z)} \]

then, \( F_{5e}(z) = (z^2 + \sigma_1 z + 1), \quad 0 \leq |\sigma_i| < 2, \)

Step3, we select \( \gamma_3 = \sigma_1 \), for \( kc(3) \),

2) In step2, if we select \( \gamma_2 = \zeta_2 \), instead of \( \zeta_1 \), for \( kc(2) \),

\[ \frac{F_{5e}(z)}{F_{1e}(z)} = kc(1) \frac{(z^2 - 1)}{\left(\frac{z^2 + \alpha_1 z + 1}{z^2 + \zeta_1 z + 1}\right)} + \frac{1}{F_{3e}(z)} \]

then, \( F_{5e}(z) = (z^2 + \zeta_1 z + 1) \quad 0 \leq |\zeta_i| < 2, \)

Then, in step3, we select \( \gamma_3 = \zeta_1 \), for \( kc(3) \)

This example has given the values of \( \gamma_i \) respectively in two groups when we select \( \gamma_2 = \zeta_1 \) or \( \gamma_2 = \zeta_2 \) for \( kc(2) \); that means that there are two options to select subpolynomial \((z^2 + \zeta_1 z + 1)\) or \((z^2 + \zeta_2 z + 1)\) of \( F_{3e}(z) \) as the denominators \( z^2 + \gamma_2 z + 1 \) of the continued fraction expansion. If we select the first subpolynomial \((z^2 + \zeta_1 z + 1)\) of \( F_{3e}(z) \) as the denominators \( z^2 + \gamma_2 z + 1 \) of the continued fraction expansion; then obtain \( \gamma_1 \), \( \gamma_2 \) and \( \gamma_3 \) in the first group as the following respectively,

\[ \alpha_1, \zeta_1, \sigma_1 \]

If we select the second subpolynomial \((z^2 + \zeta_2 z + 1)\) of \( F_{3e}(z) \) as denominators \( z^2 + \gamma_2 z + 1 \) of the continued fraction expansion; then obtain \( \gamma_1 \), \( \gamma_2 \) and \( \gamma_3 \) in the second group as the following respectively,

\[ \alpha_1, \zeta_2, \zeta_1 \]
3) If in Step1, we first select \( \gamma_1 = \alpha_2 \), for \( kc(1) \); then, \( \gamma_2 \) and \( \gamma_3 \) will be different from the above values

\[ \alpha_1, \zeta_1, \sigma_1 \]

or

\[ \alpha_1, \zeta_2, \zeta_1 \]

4) Similarly, we first select \( \gamma_1 = \alpha_3 \), for \( kc(1) \), then, \( \gamma_2 \) and \( \gamma_3 \) will be different again.

Now, we get the conclusion, the values of \( \gamma_i \) are different in each group depending on the order of the subpolynomials which are selected as the denominators of continued fraction expansions.

\[
\begin{array}{ccc}
\alpha_1 & \zeta_1 & \sigma_1 \\
\alpha_1 & \zeta_2 & \zeta_1 \\
\vdots & & \\
\vdots & & \\
\vdots & & \\
\vdots & & \\
\end{array}
\]

Let \( N_{coe} = \frac{n}{2} \), when \( n = \text{even} \)

\[ = \frac{n-1}{2}, \text{ when } n = \text{odd} \]

where \( n \) is the degree of mirror-image polynomial or anti-mirror-image polynomial in Matlab function cfekc.m, we suggest that the coefficients of rootsele vector are the subscript values of \( \alpha_1, \zeta_1, \sigma_1 \) and \( \alpha_1, \zeta_2, \zeta_1 \) and so on respectively.

For example, for the above example, one of \( z^2+\gamma_i z+1 \) terms is \( z^2+\alpha_1 z+1, z^2+\zeta_1 z+1 \) and \( z^2+\sigma_1 z+1 \) respectively, so

\[ \alpha_1, \zeta_1, \sigma_1 \xrightarrow{\text{subscript}} 1, 1, 1, \]

18
then, rootsele=[1 1 1].

Another \( z^2 + \gamma_i z + 1 \) term is \( z^2 + \alpha_1 z + 1, z^2 + \zeta_2 z + 1, z^2 + \zeta_1 + 1 \), so

\[
\alpha_1, \zeta_2, \zeta_1 \rightarrow 1, 2, 1,
\]

then, rootsele=[1 2 1].

......

The maximum number of different terms in \( kc(1), kc(2)\ldots \) and \( \gamma(1), \gamma(2)\ldots \) = \( N_{coe} \times (N_{coe} - 1) \times (N_{coe} - 2) \times \ldots 3 \times 2 \times 1 \)

The table below gives the coefficients for each of rootsele vectors to obtain the different \( kc \) and \( \gamma \) terms for MATLAB function cfekc.m, and we can produce the different \( kc \) and \( \gamma \) vectors correspondingly when we run function cfekc.m.

</table>
From the table,

1) If $Ncoe = 1$,

The number of different terms in $kc(1), kc(2), \ldots$ and $\gamma(1), \gamma(2) = Ncoe \times (Ncoe - 1) \times (Ncoe - 2) \times \ldots 3 \times 2 \times 1 = 1$. As a result, the only one is that rootsele = $[1]$. The length of rootsele vector = $Ncoe = 1$.

2) If $Ncoe = 2$,

The number of different terms in $kc(1), kc(2), \ldots$ and $\gamma(1), \gamma(2) = Ncoe \times (Ncoe - 1) \times (Ncoe - 2) \times \ldots 3 \times 2 \times 1 = 2 \times 1$. As a result, the two rootseles are $[1 \ 1]$ and $[2 \ 1]$. The length of each rootsele vector = $Ncoe = 2$.

3) If $Ncoe = 3$,

The number of different terms in $kc(1), kc(2), \ldots$ and $\gamma(1), \gamma(2) = Ncoe \times (Ncoe - 1) \times (Ncoe - 2) \times \ldots 3 \times 2 \times 1 = 3 \times 2 \times 1$. As a result, the six rootseles are $[1 \ 1 \ 1]$, $[1 \ 2 \ 1]$, $[2 \ 1 \ 1]$, $[2 \ 2 \ 1]$, $[3 \ 1 \ 1]$ and $[3 \ 2 \ 1]$ respectively. The length of each rootsele vector = $Ncoe = 3$.

4) If $Ncoe = m$, $m$ is an integer,

The total number of different terms in $kc(1), kc(2), \ldots$ and $\gamma(1), \gamma(2) = Ncoe \times (Ncoe - 1) \times (Ncoe - 2) \times \ldots 3 \times 2 \times 1 = m \times (m - 1) \times (m - 2) \times \ldots 3 \times 2 \times 1$.

$rootsele(1) = 1, 2, 3 \ldots m$

$rootsele(2) = 1, 2, 3 \ldots (m - 1)$

$rootsele(3) = 1, 2, 3 \ldots (m - 2)$

$\ldots$

$rootsele(m - 2) = 1, 2, 3$

$rootsele(m - 1) = 1, 2$

$rootsele(m) = 1$

The length of each rootsele vector = $Ncoe = m$.

5) If $n = 1$, rootsele = any value.

But not all rootseles can be determined as $kc$ and $\gamma$. For example, assume,
\[ n = 6, \ D(z) = 33.7972z^6 + 26.2840z^4 + 3.8596z^2 + 0.0592. \]

\[ F_{1e} = (z^2 + a_1z + 1)(z^2 + a_2z + 1)(z^2 + a_3z + 1), \ 0 \leq |a_i| < 2 \]

\[ = (z^2 + 1.4524z + 1)(z^2 - 1.4524z + 1)(z^2 + 1) \]

\[ F_{2e} = 16.8690z^6 + 11.2122z^4 - 11.2122z^2 - 16.8690 \]

and if we set rootsele = [1 2 1].

Step 1: because \text{rootsele}(1) = 1, so, we select the first subpolynomial \((z^2 + 1.4524z + 1)\) of \(F_{1e}(z)\) as the denominator \(z^2 + \gamma_1z + 1\) of the continued fraction expansion, \(\gamma_1 = 1.4524.\)

\[ \frac{F_{2e}(z)}{F_{1e}(z)} = 0.4191 \frac{(z^2-1)}{(z^2+1.4524z+1)} + \frac{1}{F_{3e}(z)}, \text{ and } k(1) = 0.4191. \]

It is easy to find \(F_{3e} = (z^2 - 0.3984z + 1)(z^2 - 1)\)

\[ F_{4e} = 16.928z^4 - 24.5877z^3 + 33.8564z^2 - 24.5877z + 16.9282 \]

Step 2: because \text{rootsele}(2) = 2, so, we select the second subpolynomial \((z^2-1)\) of \(F_{3e}(z)\) as the denominator \(z^2 + \gamma_2z + 1\) of the continued fraction expansion. As we have known before, this condition, the zeros of \(z^2 + \gamma/z + 1\) are strictly inside the unit circle, must be satisfied, so \((z^2 - 1)\) can't be as the denominator \(z^2 + \gamma_2z + 1.\)

As a result, there is no solution for \text{rootsele} = [1 2 1].

### 2.3 Implementation of Algorithms for Coefficient Determination

2.4 Summary and Discussion

In this chapter, a new type of \( z \) - domain continued fraction expansion CFE4 has been introduced. It is known that this type of CFE4 is always possible for a rational function formulated by the ratio \( \frac{F_{2e}(z)}{F_{1e}(z)} \) or \( \frac{F_{2e}(z)}{F_{1e}(z)} \) of anti - mirror - image polynomial to mirror - image polynomial, which are obtained by a Schur polynomial containing all its zeros within the unit circle. The coefficients of this CFE are of the type given in Eqs (2.18) and Eqs (2.20). It is also shown that this type of CFE is non-unique as compared with the other three types of CFEs - CFE1, CFE2 and CFE3, which are unique. This is because the coefficients of CFE4 are dependent on the poles and zeros of the \( \frac{F_{2e}(z)}{F_{1e}(z)} \) or \( \frac{F_{2e}(z)}{F_{1e}(z)} \). Algorithms have been given in order to obtain all possible CFE4's.
Chapter 3

The New Continued Fraction Expansion for Butterworth Lowpass Filter and Butterworth Lowpass CCPF Filter in z Domain

Generally, Butterworth lowpass filter approximations are based in Laplace transform domain[11] and [12]. By applying the bilinear transformation $s = \frac{z-1}{z+1}$, the transfer functions in discrete domain are characterized. In this chapter, we shall obtain the denominator polynomials of Butterworth lowpass filters of different order and also the coefficients in the various continued fraction expansions.

In addition, we shall discuss the new family of transitional filters - Complementary Pole-pair Filters (CPPFs) [13], whose design is based on the judicious position of symmetry poles in the $s$-plane. For such filters also, we obtain the coefficients in the various continued fraction expansions.
3.1 The Application of the Continued Fraction Expansion for Butterworth Lowpass Filter in $z$ domain

First we take the $n$th-order Butterworth lowpass filter polynomial in $s$ domain, and by applying the bilinear transformation $s = k \frac{z-1}{z+1}$, we obtain the digital lowpass transfer functions

$$T_{BD} = \frac{N_d(z)}{D_d(z)} = \frac{(z + 1)^n}{D_{BD}(z)} \quad (3.1)$$

In this thesis, $k$ is chosen to be unity. For each order of $D_{BD}(z)$, the Butterworth polynomials in the $z$ - domain are obtained which are listed in Table 3.1 up to order $n = 8$. For these polynomials, the mirror-image polynomial $F_{BD1}(z)$ and the anti-mirror-image polynomials $F_{BD2}(z)$ are obtained and listed in Table 3.2.

The following algorithm, called butterworthkakb.m, is employed to obtain \( ka \) and \( kb \) coefficients of continued fraction expansions for a \( n \)th-order denominator of Butterworth lowpass filter polynomial in \( z \) domain.

Algorithm 7: Matlab Function butterworthkakb.m

```matlab
function [ka, kb] = butterworthkakb(d)

%% This function calculates the Butterworth filter coefficients

%% \( d \) is a vector which represents the coefficients of a denominator polynomial

%% of Butterworth filter respectively in descending powers of \( s \) domain,

%% applying bilinear transformation \( s = \frac{z^{-1}}{z+1} \), we get \( T_{Bd} = k_B \frac{N_{Bd}(z)}{D_{Bd}(z)} = \frac{(z+1)^n}{D_{Bd}(z)} \),

%% 39
```
% $D_{Bd}(z)$ is a denominator polynomial of Butterworth filter in z domain.
% Find coefficients ka and kb of the continued-fraction expansion (CFE) of
% $F_{B1}(z)/F_{B2}(z)$ or $F_{B2}(z)/F_{B1}(z)$, where $F_{B1}(z)$ is mirror-image
% polynomial, and $F_{B2}(z)$ is antimirror-image polynomial of $D_{Bd}(z)$.
% $F_{B1}(z) = \frac{[D_{Bd}(z) + z^n D_{Bd}(z^{-1})]}{2}$
% $F_{B2}(z) = \frac{[D_{Bd}(z) - z^n D_{Bd}(z^{-1})]}{2}$
%
% CFE1:
% For $n$ = even or odd,
% $$\frac{F_{B1}(z)}{F_{B2}(z)} = ka(1) \left(\frac{z+1}{z-1}\right) + \frac{1}{ka(2) \left(\frac{z+1}{z-1}\right) + \frac{1}{ka(3) \left(\frac{z+1}{z-1}\right) + \ldots}}$$
%
% CFE2:
% For $n$ = even,
% $$\frac{F_{B1e}(z)}{F_{B2e}(z)} = kb(1) \left(\frac{z-1}{z+1}\right) + \frac{1}{kb(2) \left(\frac{z-1}{z+1}\right) + \frac{1}{kb(3) \left(\frac{z-1}{z+1}\right) + \ldots}}$$
% Or if $n$ = odd,
% $$\frac{F_{B1o}(z)}{F_{B2o}(z)} = kb(1) \left(\frac{z-1}{z+1}\right) + \frac{1}{kb(2) \left(\frac{z-1}{z+1}\right) + \frac{1}{kb(3) \left(\frac{z-1}{z+1}\right) + \ldots}}$$
% Convert $F_{B1}(z)/F_{B2}(z)$ or $F_{B2}(z)/F_{B1}(z)$ to continued fraction expansions
%
% $d(1)$ must be non-negative.
if( $d(1) <= 0$ )
    error('First coefficient in d vector must be non-negative.')
    return
end
%
% The coefficient of d vector must be real
for ii = 1:length(d)
    if( any(imag(d(ii))))
        error('The coefficient of d vector must be real value.')
    end
end
return
end
end

% Get ka and kb coefficients of the continued-fraction expansion

$[Nd,Dd]=\text{bilinear}(1,d,0.5);$ 
$\text{denpoly}=Dd/Nd(1);$ 
$[ka,\text{kb}]=\text{cfekak}(\text{denpoly});$

The following table 3.3 gives the coefficients ka's of CFE1 for denominators of Butterworth lowpass polynomials.

$d$ is a vector which represents the coefficients of a denominator polynomial of Butterworth lowpass filter respectively in descending powers of $s$ domain, in the form $s^n + a_1 s^{n-1} + a_2 s^{n-2} + \ldots + a_{n-2} s^2 + a_{n-1} s + 1$, for a Butterworth filter function of the order $n$, with pass-band from 0 to 1 rad/sec. By applying bilinear transformation $s = \frac{z-1}{z+1}$, we present $T_{Bd} = \frac{N_d(z)}{D_d(z)} = \frac{(z+1)^n}{D_{Bd}(z)}$, $D_{Bd}(z)$ is a denominator polynomial of Butterworth lowpass filter in $z$ domain. ka's are coefficients of the continued-fraction expansion (CFE1) of $F_{B1}(z)/F_{B2}(z)$, where $F_{B1}(z)$ is mirror-image polynomial, and $F_{B2}(z)$ is antimirror-image polynomial of $D_{Bd}(z)$.

The algorithm, called butterworthkc.m, is employed to compute \( kc \) or \( k0 \) and \( \gamma \) coefficients of \( CFE4 \) for a \( n \)th-order denominator of Butterworth lowpass filter polynomial.

Algorithm 8: Matlab Function butterworthkc.m

```matlab
function [k0, kc, r] = butterworthkc(d, rootsel)

%%
%% d is a vector which represents the coefficients of a denominator polynomial
%% of Butterworth filter respectively in descending powers of s domain,
%% applying bilinear transformation \( s = \frac{z-1}{z+1} \), we get \( T_{BD} = \frac{N_d(z)}{D_d(z)} = \frac{(z+1)^n}{D_{BD}(z)} \),
%% \( D_{BD}(z) \) is a denominator polynomial of Butterworth filter in z domain.
%% Find coefficients \( kc \) and \( r \) of the continued-fraction expansion (CFE) of
%% \( F_{B1}(z)/F_{B2}(z) \) or \( F_{B2}(z)/F_{B1}(z) \), where \( F_{B1}(z) \) is mirror-image
```

43
% polynomial, and $F_{B2}(z)$ is antimirror-image polynomial of $D_{Bd}(z)$.
% $F_{B1}(z) = \left[ \frac{D_{Bd}(z) + z^n D_{Bd}(z^{-1})}{2} \right]$
% $F_{B2}(z) = \left[ \frac{D_{Bd}(z) - z^n D_{Bd}(z^{-1})}{2} \right]$
%
% CFE4:
% For $n = odd$,
% $\frac{F_{B0}(z)}{F_{10}(z)} = kc(0) (\frac{z-1}{z+1}) + kc(1) (\frac{z^2-1}{z^2+\gamma z+1}) + \frac{1}{kc(2) (\frac{z^2-1}{z^2+\gamma z+1}) + \frac{1}{kc(3) (\frac{z^2-1}{z^2+\gamma z+1}) + \ldots}}$
%
% CFE4:
% For $n = even, kc(0)$
% $\frac{F_{B0}(z)}{F_{1e}(z)} = kc(1) (\frac{z^2-1}{z^2+\gamma z+1}) + \frac{1}{kc(2) (\frac{z^2-1}{z^2+\gamma z+1}) + \frac{1}{kc(3) (\frac{z^2-1}{z^2+\gamma z+1}) + \ldots}}$

%%% Convert $F_2(z)/F_1(z)$ to continued fraction expansions %%

% $d(1)$ must be non-negative.
if( $d(1) \leq 0$ )
    error('First coefficient in d vector must be non-negative.\n')
    return
end

% The coefficient of d vector must be real value
for ii = 1:length(d)
    if( any(imag(d(ii))))
        error('The coefficient of d vector must be real value.\n')
        return
    end
end

%%% Get kc and r coefficients of the continued-fraction expansion
\([Nd, Dd] = \text{bilinear}(1, d, 0.5)\);

denpoly = \frac{Dd}{Nd(1)};

\([k0, kc, r] = \text{cfekc}(\text{denpoly}, \text{rootsele})\);

The following table 3.6 gives the values of coefficients \(kc's\) and \(\gamma's\) in \(CFE4\) for denominators of Butterworth lowpass filters.

We present \(T_{Bd} = \frac{N_d(z)}{D_d(z)} = \frac{(z+1)^n}{D_{Bd}(z)}\). \(kc\) and \(\gamma\) are coefficients of the continued-fraction expansion (\(CFE4\)) of \(F_{B2}(z)/F_{B1}(z)\), where \(F_{B1}(z)\) is mirror-image polynomial, and \(F_{B2}(z)\) is antimirror-image polynomial of \(D_{Bd}(z)\).

3.2 The Application of the Continued Fraction Expansion for Butterworth Lowpass CPPF Filter in z domain

3.2.1 Pole-parameter Representation [10]

In following section, we give a brief summary of the Pole-Parameter Representation and Complementary Pole -pair Filters. We will introduce the terminology, "pole-parameters". The line which joins any pole with the origin of the co-ordinates is referred to as the "pole-phasor". The magnitude \( \omega_p \) and the angle \( \theta_p \) of pole-phasor are shown in figure below, wherein the pole-parameters \((\omega_p, \theta_p)\) corresponding to a negative real pole \((s_r)\) and a complex conjugate pole-pair \((s, s*)\) are defined. In addition, the pole-parameter \( \omega_p \) is "pole-frequency", and the polar-angle \( \theta_p \) is related to the pole-\( Q \).

\[
Q_p = \frac{1}{2 \cos(\theta_p)}
\]
3.2.2 Complementary Symmetry Among Butterworth Poles [10]

For a specified order Butterworth filter, the poles located uniformly on the left-half of \( s \)-plane, on second and third quadrant, on the unit circle, are symmetrical about the horizontal axis, and exhibit a mirror-image symmetry. Therefore all poles on the left-half plane of the \( s \)-plane can be expressed just by poles on the second-quadrant only. In addition, for a \( n \)-th order Butterworth filter, the pole-parameters corresponding to poles in the second-quadrant can be written as follows:

\[
\omega_p = 1 \begin{cases} 
   k = 1, 2, \ldots \frac{n}{2} & \text{for } n \text{ even} \\
   k = 0, 1, 2, \ldots \frac{n-1}{2} & \text{for } n \text{ odd}
\end{cases}
\]  

(3.2)

and
\[ \theta_{pk} = \begin{cases} 
\frac{(2k-1)\pi}{2n} & k = 1, 2, \ldots \frac{n}{2}, \text{ for } n \text{ even} \\
\frac{k\pi}{n} & k = 0, 1, 2, \ldots \frac{n-1}{2}, \text{ for } n \text{ odd} 
\end{cases} \tag{3.3} \]

The squared-magnitude of this Butterworth filter is

\[ A^2(\omega) = \frac{1}{1+\omega^{2n}} \]

For the general case, all pole-phasors have magnitudes equal to \( \omega_p \) (not necessarily unity), and the polar angles \( \theta_{pk} \) are related at values given by the Eqn (3.3). Furthermore, we normalize the d.c. values of \( A(\omega) \) to unity at \( \omega = 0 \) (at DC), so that \( A(\omega) \) at \( \omega = 0 \) is independent of \( \omega_p \); then, we can write the squared-magnitude of transfer function,

\[ A^2(\omega) = \frac{\omega_p^{2n}}{\omega_p^{2n}+\omega^{2n}} \]

In general, for any odd or even order Butterworth filter, the poles exhibit half-plane symmetry properties with respect to both real and imaginary axis. Based on the fact that even order filters (order is \( 2^k \), \( k \) is integers) exhibit additional symmetry properties, for example, \( n = 16 \), from Eqn (3.3), we get

\[
\begin{bmatrix}
\theta_1 = \frac{\pi}{32} & \theta_8 = \frac{15\pi}{32} \\
\theta_2 = \frac{3\pi}{32} & \theta_7 = \frac{13\pi}{32} \\
\theta_3 = \frac{5\pi}{32} & \theta_6 = \frac{11\pi}{32} \\
\theta_4 = \frac{7\pi}{32} & \theta_5 = \frac{9\pi}{32}
\end{bmatrix}
\]
Figure 3.2: $s$-plane Pole-pattern of the Butterworth Filter of $n = 16$

We can easily find adjacent Butterworth poles in the second quadrant possess another symmetry - the adjacent pole-pairs $(s_1, s_2), (s_3, s_4), (s_5, s_6), (s_7, s_8)$ are symmetrical about the lines $OA, OB, OC$ and $OD$ whose angles are $\frac{\pi}{16}, \frac{3\pi}{16}, \frac{5\pi}{16}, \frac{7\pi}{16}$ respectively, and each of the four symmetrical pairs adds up to $\frac{\pi}{2}$.

$$(\theta_1 + \theta_2) = (\theta_2 + \theta_7) = (\theta_3 + \theta_6) = (\theta_4 + \theta_5) = \frac{\pi}{2}$$

We designate such pole-pairs, whose $\theta_p$ values add up to $\frac{\pi}{2}$, as "Complementary Pole Pairs (CPPs)."

$$(\theta_\Gamma + \theta(\frac{\pi}{2} - \Gamma + 1)) = \frac{\pi}{2}, \quad \Gamma = 1, 2, \ldots, \frac{n}{4}$$
3.2.3 Modification of Butterworth Pole-pattern Preserving the CPPF Properties [10]

If we swing the pole-vectors of each adjacent pole-pair about Butterworth filters by equal angle $\theta_0$ toward the respective axes of symmetry, the new set of polar angles will be

\[
\begin{align*}
\theta_1 &= \frac{\pi}{32} + \theta_0 \\
\theta_2 &= \frac{3\pi}{32} - \theta_0 \\
\theta_3 &= \frac{5\pi}{32} + \theta_0 \\
\theta_4 &= \frac{7\pi}{32} - \theta_0 \\
\theta_5 &= \frac{9\pi}{32} + \theta_0
\end{align*}
\]

Figure 3.3: s-plane Pole-pattern of the CPPF of $n = 16$
The reference pole-pattern of any specified order \( n = 2^k \) Butterworth filter can be modified as:

\[
\theta'_{k} = \frac{(2k - 1)\pi}{2n} + (-1)^{k-1}\theta_0, \quad k = 1, 2, \ldots, \frac{n}{2}
\]  

(3.4)

where \( \theta_0 < \frac{\pi}{2n} \).

When \( \theta_0 > 0 \), modified transfer function is a low-Q filter (LQF), or \( \theta_0 < 0 \), it is a high-Q filter (HQF).

Then, we can see the second-order transfer function corresponding to a complex conjugate pole-pair with \( \omega_{pk} \) as magnitude and \( \pm\theta_{pk} \) as pole-parameters can be obtained as

\[
T_k(s) = \frac{\omega_{pk}^2}{s^2 + 2\omega_{pk}\cos(\theta_{pk})s + \omega_{pk}^2}
\]

(3.5)

Furthermore, it is easy to get a nth-order \( T(s) \) transfer function, which is the product of all \( T_k(s) \).

\[
T(s) = \Pi T_k(s), \quad k = 1, 2, \ldots, \frac{n}{2}
\]

(3.6)

The algorithm, called cppkakb.m, is employed to compute \( ka \) and \( kb \) coefficients of continued fraction expansions of CPP filters.

3.3 Summary and Discussion

This chapter gives the algorithms for obtaining the coefficients of the different continued fraction expansions for the $z$-domain denominator polynomials corresponding to Butterworth lowpass filters and complementary pole-pair lowpass filters.
Chapter 4

The Application of the Continued Fraction Expansion for Chebyshev Lowpass Filter in $z$ Domain

Chebyshev lowpass filter approximations are based on Laplace domain. By applying the bilinear transformation $s = \frac{z-1}{z+1}$, the transfer functions in discrete domain are characterized.

The purpose of this chapter is to establish an algorithm to obtain the coefficients $ka$'s, $kb$'s and $kc$'s and $\gamma$'s of continued fraction expansion (CFE) using the concept of mirror-image polynomial and anti-mirror-image polynomial for Chebyshev lowpass filters in $z$ domain after bilinear transformation.
4.1 The Application of the Continued Fraction Expansion for Chebyshev Lowpass Filter in $z$ domain

First we take the $n$th-order Chebyshev lowpass filter polynomial, and apply bilinear transformation $s = \frac{z - 1}{z + 1}$, then we will get lowpass transfer functions in discrete domain $T_{CD}(z) = \frac{N(z)}{D(z)} = \frac{(z + 1)^n}{D_{CD}(z)}$. For each order of $D_{CD}(z)$, we can produce the mirror-image and anti-mirror-image polynomials.

Each order of $D_{CD}(z)$, the denominator polynomial of Chebyshev lowpass filters in the $z$ - domain, is obtained which is listed in Table 4.1 up to order $n = 6$. For these polynomials, the mirror-image polynomial $F_{CD1}(z)$ and the anti-mirror-image polynomials $F_{CD2}(z)$ are obtained and are listed in Table 4.2.

The following algorithm, called chebyshevkakb.m, is employed to obtain $ka$ and $kb$ coefficients of continued fraction expansions for a nth-order denominator polynomial of Chebyshev lowpass filter.

Algorithm 11: Matlab Function chebyshevkakb.m

```matlab
function [ka, kb] = chebyshevkakb(d)

% d is a denominator polynomial of Chebyshev filter in s domain, apply
% bilinear transformation $s = \frac{z-1}{z+1}$, we get $T_{CHa}(z) = kCH^{N_{CHd}(z)}D_{CHd}(z) = \frac{(z+1)^n}{D_{CHd}(z)}$
% $D_d(z)$ is a denominator polynomial of Chebyshev filter in z domain.
% Find coefficients $ka$ and $kb$ of the continued-fraction expansion (CFE) of
% $F_1(z)/F_2(z)$ or $F_2(z)/F_1(z)$, where $F_1(z)$ is mirror-image polynomial,
% and $F_2(z)$ is antimirror-image polynomial of $D_d(z)$.
% $F_1(z) = \frac{D_d(z)+z^nD_d(z^{-1})}{2}$
% $F_2(z) = \frac{D_d(z)-z^nD_d(z^{-1})}{2}$
%
% CFE1:
% For $n = even$ or odd,
% $F_1(x)F_2(x) = k(1)\frac{(z+1)}{(z-1)} + \frac{1}{ka(2)}\frac{(z-1)}{(z+1)} + \frac{1}{ka(3)}\frac{(z-1)}{(z+1)^2} + \cdots$
% CFE2:
% For $n = even$,
% $F_1(x)F_2(x) = lb(1)\frac{(z-1)}{(z+1)} + \frac{1}{kb(2)}\frac{(z-1)}{(z+1)} + \frac{1}{kb(3)}\frac{(z-1)}{(z+1)^2} + \cdots$
% Or if $n = odd$,
% $F_1(x)F_2(x) = kb(1)\frac{(z-1)}{(z+1)} + \frac{1}{kb(2)}\frac{(z-1)}{(z+1)} + \frac{1}{kb(3)}\frac{(z-1)}{(z+1)^2} + \cdots$
% $d$ is coefficients of polynomial $D$ respectively in descending powers of $z$.
% $\%\%$ Convert $F_1(z)/F_2(z)$ or $F_2(z)/F_1(z)$ to continued fraction expansions $\%\%$
```

66
\% d(1) must be non-negative.

if( d(1) <= 0 )
    error('First coefficient in d vector must be non-negative.')
    return
end

\% The coefficient of d vector must be real value

for ii = 1:length(d)
    if( any(imag(d(ii))))
        error('The coefficient of d vector must be real value.')
        return
    end
end

\% Get ka and kb coefficients of the continued-fraction expansion

[Nd,Dd]=bilinear(1,d,0.5);

denpoly=Dd/Nd(1);

[ka,kb]=cfekab(denpoly);

The following table 4.3 gives the coefficients ka's of CFE1 for denominator polynomials of Chebyshev lowpass filters.

d is a vector which represents the coefficients of a denominator polynomial of Chebyshev filter respectively in descending powers of s domain, in the form \( s^n + a_1 s^{n-1} + a_2 s^{n-2} + ... + a_{n-2} s^2 + a_{n-1} s + a_n \), for Chebyshev filter function of order n, with pass-band from 0 to 1 rad/sec. By applying bilinear transformation \( s = \frac{z-1}{z+1} \), we get \( T_d = \frac{N_d(z)}{D_d(z)} = \frac{(z+1)^n}{D_d(z)} \), \( D_d(z) \) is a denominator polynomial of Chebyshev lowpass filter in z domain. \( ka \) are coefficients of the continued-fraction expansion (CFE) of \( F_1(z)/F_2(z) \), where \( F_1(z) \) is mirror-image polynomial, and \( F_2(z) \) is antimirror-image polynomial of \( D_d(z) \).

### 4.2 Summary and Discussion

This chapter gives the algorithms for obtaining the coefficients of the different continued fraction expansions $CFE$ for the $z$-domain denominator polynomials corresponding to Chebyshev lowpass filters.
Chapter 5

The Generation of the Transfer Functions

The previous chapters dealt with the determination of the coefficients of continued fraction expansions using the concept of mirror-image polynomial and anti-mirror-image polynomial for Butterworth lowpass filter, Butterworth lowpass CPPF filter and Chebyshev lowpass filter approximations in z domain after bilinear transformation.

It must be noted that the positivity of \( k\gamma' \)s will not be sufficient to prove that \( D(z) \) contains all its zeros within the unit circle. However, when CFEs in this thesis are considered, \( k\gamma' \)s are positive, and magnitudes of \( \gamma_i \)'s are less than 2. From these, stable transfer functions \( D(z) \) can be obtained. The purpose of this chapter is to establish an algorithm to obtain stable transfer functions of the filters in z domain from coefficients \( k_c \) and \( \gamma \) of the continued fraction expansions (CFE4). For example, we would like to use coefficients \( k_0 \), \( k_c \) and \( \gamma \) of continued fraction expansions for Butterworth lowpass filters, Butterworth CPPF's filter and Chebyshev lowpass filter approximations in z domain, which are obtained in chapter 3 and chapter 4, to get the transfer functions of the filters.
5.1 Generation of the Stable Transfer Functions from Coefficients $kc$ and $\gamma$ of Continued Fraction Expansion

5.1.1 Lowpass Filter

a) 

Given $kc$ (and $k_0$) and $\gamma$ coefficients of a continued fraction expansion for a lowpass filter, we can easily represent the denominator $D_d(z)$ of transfer function in $z$ domain whose zeros are satisfied inside the unit circle.

$$T(z) = \frac{N_d(z)}{D_d(z)} = \frac{(z + 1)^n}{D_d(z)} \quad (5.1)$$

We can normalize Equ (5.1) to make the maximum of $T_{ld}(z)$ unity.

For a $n$th-order lowpass filter transfer function, we will get digital transfer function

$$T_{ld} = \frac{(z + 1)^n}{D_{ld}(z)} \quad (5.2)$$

b) 

The code dlowpoly.m used to design the denominators of lowpass filter transfer functions is given below. Then we select 3 frequencies randomly in passband to examine the magnitude values of lowpass filter transfer functions. The range of 3 frequencies are $[0, 2\times\arctan(1)]$.

The M-file dlowpoly.m is employed to examine the magnitude values of lowpass filter transfer functions coming from $k_0$, $kc$ and $\gamma$ coefficients of continued fraction expansions.
function [wl, Maglow] = dlowpoly(k0,kc,r)

% d(z) = F_1(z) + F_2(z)

% \frac{F_{2o}(z)}{F_{1o}(z)} = kc(1) \frac{(z^{-1})}{(z+1)} + kc(1) \frac{(z^2-1)}{(z^2+\gamma_1 z+1)} + \frac{1}{kc(2) \frac{(z^2-1)}{(z^2+\gamma_2 z+1)} + \frac{1}{\frac{1}{kc(3) \frac{(z^2-1)}{(z^2+\gamma_3 z+1)} + \ldots}}}

% k0, kc are coefficients of the continued-fraction expansion for a
% denominator of lowpass
% r are coefficients of \(z^2 + \gamma(n)z + 1\) respectively
% Maglow is the vector of magnitudes values at \(wl\) in \([0, 2*arctan(1)]\)
% randomly
% Obtain a denominator polynomial from coefficients of CFE

5.1.2 Highpass Filter

a) Using $s \rightarrow \frac{1}{s}$ transformation or m-file lp2hp, $\omega_0 = 1$, a highpass filter, whose cutoff frequency is 1, can be produced from a lowpass filter in $s$ domain.

b) First we take the nth-order highpass filter polynomial in $s$ domain, and by applying the bilinear transformation $s = \frac{z-1}{z+1}$, we obtain a nth-order highpass filter transfer function in discrete domain.

$$T_{hd} = \frac{N_d(z)}{D_d(z)} = \frac{(z - 1)^n}{D_{hd}(z)}$$ (5.3)

c) The m-files of dhighbutter.m, dhigcpp.m and dhigcheby.m, which are used to examine the magnitude values of highpass filter transfer functions, are given below.
Then we select 3 frequencies randomly in passband, and the range of 3 frequencies is \([2 \times \arctan(1), \pi]\).

The M-file dhighbutter.m is employed to examine the magnitude values of highpass filter transfer functions for Butterworth filters.

---

Algorithm 15: Matlab function dhighbutter.m

```matlab
function [wh, Maghighbutter] = dhighbutter(N)

% N is the order of Butterworth filters
% Maghighbutter is the vector of magnitudes values at wh in
% [2*arctan(1), \pi] randomly

[nums, dens] = butter(N, 1, 'high', 's');
[NUMZ, DENZ] = bilinear(nums, dens, 0.5);
wh = 4*atan(1) - 2*atan(1)*rand(1, 3);
Maghighbutter = abs(freqz(NUMZ, DENZ, wh));
w = 0.01:0.01:pi;
highpass = freqz(NUMZ, DENZ, w);
plot(w, abs(highpass));
xlabel('\omega');
ylabel('Frequency Response of Highpass');
axis([0 pi 0 1.0])
```

5.1.3 Bandpass Filter

a) Using $s \rightarrow \frac{s^2 + \Omega_0^2}{s B_\omega}$ transformation or m-file *lp2hp*, a bandpass filter can be produced from a lowpass filter in $s$ domain; for example, center frequency $\Omega_0 = 1$, and bandwidth $B_\omega = 1$.

b) First we take the $n$th-order bandpass filter polynomial in $s$ domain, and by applying the bilinear transformation $s = \frac{z-1}{z+1}$, we obtain a $n$th-order bandpass filter transfer function in discrete domain.

$$T_{bd} = \frac{N_d(z)}{D_d(z)} = \frac{(z^2 - 1)^{\frac{n}{2}}}{D_{bd}(z)}$$  (5.4)
c)

The M-files of dbandbutter.m, dbandcpp.m and dbandcheby.m, which are used to examine the magnitude values of bandpass filter transfer functions, are given below. Then we select 3 frequencies randomly in passband, and the range of 3 frequencies is \([ 2 \times \arctan(0.6180), 2 \times \arctan(1.6180)]\).

The M-file dbandbutter.m is employed to examine the magnitude values of bandpass filter transfer functions for Butterworth filters.

Algorithm 18: Matlab function dbandbutter.m

```matlab
function [wb, Magbandbutter] = dbandbutter(N)
% N is the order of Butter filters
% Magbandbutter is the vector of magnitudes values at wb in
% [ 2*arctan(0.6180), 2*arctan(0.6180)] randomly

[b,a]=butter(N,1,'s');
[nums,dens]=lp2bp(b,a,1,1);
[NUMZ,DENZ]=bilinear(nums,dens,0.5);
wb = 2*atan(0.6180)+(2*atan(1.6180)-2*atan(0.6180))*rand(1,3);
Magbandbutter=abs(freqz(NUMZ,DENZ,wb));

w=0.01:0.01:pi;
bandpass = freqz(NUMZ,DENZ,w);
plot(w,abs(bandpass));

xlabel('\omega');
ylabel('Frequency Response of Bandpass');
axis([0 pi 0 1.0])
```

5.2 Summary and Discussion

In this chapter techniques are developed for establishing algorithms to obtain stable transfer functions of filters in $z$ domain from coefficients $kc$ and $\gamma$ of the continued fraction expansions ($CFE4$).

The chapter has also considered the computer-aided design of filters.
Chapter 6

Summary and Discussion

In this thesis, the following three types of continued fraction expansions $CFE1$, $CFE2$ and $CFE3$ have been discussed.

1) $CFE1$:

For $n$ is even or odd,

$$\frac{F_{1}(x)}{F_{2}(x)} = ka(1) \frac{(x+1)}{(x-1)} + \frac{1}{ka(2) \frac{(x+1)}{(x-1)} + \frac{1}{ka(3) \frac{(x+1)}{(x-1)} + \ldots}}$$

where $ka(1), ka(2) \ldots ka(n)$ are real and positive.

2) $CFE2$:

(a) $CFE2a$:

For $n$ is even,

$$\frac{F_{10}(x)}{F_{20}(x)} = kb(1) \frac{(x-1)}{(x+1)} + \frac{1}{kb(2) \frac{(x-1)}{(x+1)} + \frac{1}{kb(3) \frac{(x-1)}{(x+1)} + \ldots}}$$

where $kb(1), kb(2) \ldots kb(n)$ are real and positive.

(b) $CFE2b$:

If $n$ is odd,

$$\frac{F_{10}(x)}{F_{20}(x)} = kb(1) \frac{(x-1)}{(x+1)} + \frac{1}{kb(2) \frac{(x-1)}{(x+1)} + \frac{1}{kb(3) \frac{(x-1)}{(x+1)} + \ldots}}$$

where $kb(1), kb(2) \ldots kb(n)$ are real and positive.
3) CFE 1a
\[
\frac{F_1(z)}{F_3(z)} = r_1(z - 1) + \frac{1}{r_2(1 - z^{-1}) + \frac{1}{r_3(1 - z^{-1}) + \ldots}}
\]

4) CFE3
For n is odd,

CFE 3a
\[
\frac{F_{1a}(z)}{F_{2a}(z)} = ko(1)\frac{z+1}{z-1} + \frac{1}{ko(2)\frac{z+1}{z-1} + ko(3)\frac{z+1}{z-1} + \ldots}
\]

For n is even,

CFE 3b
\[
\frac{F_{1b}(z)}{F_{2b}(z)} = ke(1)\frac{z+1}{z+1} + ke(2)\frac{z+1}{z-1} + \frac{1}{ke(3)\frac{z+1}{z+1} + ke(4)\frac{z+1}{z-1} + \ldots}
\]

where kf and kz are real and positive.

MATLAB programmes have been developed so that the various coefficients in each continued fraction expansion can be obtained.

5) We have also produced the new type of continued fraction expansion given as follows CFE4:

For n = odd,
\[
\frac{F_{2a}(z)}{F_{1a}(z)} = kc(0)\frac{z-1}{z+1} + kc(1)\frac{z^2-1}{z^2+\gamma_1 z+1} + \frac{1}{kc(2)\frac{z^2-1}{z^2+\gamma_2 z+1} + \ldots}
\]

where \(kc(0), kc(1), kc(2)\ldots kc\left(\frac{n-1}{2}\right)\) are real and positive; \(0 \leq |\gamma_i| < 2, i = 1, 2, \ldots, \frac{n-1}{2}\).

For n = even,
\[
\frac{F_{2a}(z)}{F_{1a}(z)} = kc(1)\frac{z^2-1}{z^2+\gamma_1 z+1} + \frac{1}{kc(2)\frac{z^2-1}{z^2+\gamma_2 z+1} + \ldots}
\]

where \(kc(0) = 0; kc(1), kc(2)\ldots kc\left(\frac{n}{2}\right)\) are real and positive; \(0 \leq |\gamma_i| < 2, i = 1, 2, \ldots, \frac{n}{2}\).
Unlike the $CFE1$, $CFE2$ and $CFE3$, $CFE4$ is non-unique for a given Schur polynomial $D(z)$. This is because the $CFE$ is based on the zeros of a mirror-image or an anti-mirror image polynomial located on the unit circle. This shows that a large number of possibilities exist. Algorithms have been given to obtain the various possible $CFE4$'s for a given $D(z)$, and some have been written in MATLAB.

In addition, it is shown that given coefficients of a $CFE4$ have been shown, it is possible to obtain stable transfer functions so that filters can be designed from the coefficients of $CFE4$.

The three necessary frequency samples have been taken randomly for lowpass, highpass and bandpass respectively. The techniques produce good performance filters with good magnitude responses of lowpass, highpass and bandpass filters.

This thesis can be considered as a starting point for application of continued fraction expansions in filter design. The same methods are suggestions for any other kinds of stable filter design.
