ABSTRACT

Generalized Finite Element Dynamic Modelling And Simulation For Flexible Robot Manipulators

Zhou Feng

Generalized system modelling using finite element technique is examined in order that the dynamic behaviour of flexible robot manipulators can be studied. Most of the dynamic models currently used for robot motion simulation are restricted to open kinematic chains of rigid body elements. However, to improve dynamic performance, it is essential to take into account the structural mechanic characteristics of robot components. This thesis presents a general finite element model for flexible robots and validates them by simulation.

The kinematic equations are set up and the system kinetic and potential energies as well as their derivatives are obtained. Lagrange's formulation is employed and the generalized system dynamic equations which represent spatial performance are solved based on finite element analysis.

To validate the generalized equations developed for flexible robot manipulator, two sample simulations are carried out for 2-link and single link manipulators without and with torque. The responses are obtained, compared and discussed.
ACKNOWLEDGEMENTS

The author is sincerely grateful to his thesis supervisor Dr. T.S. Sankar, under whose research guidance this work was completed, for his ideas, help, financial assistance and continuous encouragement during the course of this investigation.

The help and assistance of many friends and colleagues, especially those of Dr. Chang-jin Li, are gratefully acknowledged.

Finally, the author is grateful to his parents for their abundant moral support and understanding throughout the course of this Masters program.

$\mu$: density of the link

$\tau$: driving torque
CHAPTER 1
INTRODUCTION

1.1 PRELIMINARIES

Most of present analysis and design for industrial robots are based on the assumption that robot arms are composed of rigid bodies. This assumption brings a lot of convenience in both analysis and study of these robot manipulators. Control systems for robot manipulators based on this assumption are designed so that the end-effector of the robot manipulator will be in a certain position after joints are driven to a given set of precomputed angular positions. But in fact, the manipulator links are not absolutely rigid. The rigidity assumption is, in fact, presumes that if the stiffness of the object is so large compared to its geometry that the influence of its flexibility may be neglected and the object could be considered as rigid. In order to keep the robot arms rigid as per design when they are performing at high speed and/or carrying heavy payloads, robot manipulators have to be built massive, hence will encounter high material cost and large energy consumption.

Noticing these drawbacks of rigid robot arm design, the concept of flexible robot manipulator is introduced to replace the analytical premise of rigid robot arm. Compared with the traditional design of rigid robot manipulators, the flexible
robot manipulators not only are able to carry equally heavy payloads and can be fast moving without having to design each link thick and strong, but also possess many advantages: they need less material, are more maneuverable, are lighter and hence consume less power, possess smaller volume and are more easily transportable [1-2].

The main obstacle preventing wide use of flexible robot manipulator is due in part to the fact that it is often difficult to obtain a reasonable accuracy of response corresponding to the input commands from the control systems [3]. At the same time, the robot model used in the design should be able to describe the identifiable behaviour of the manipulators with adequate accuracy. An improved dynamic model (i.e., the dynamic equations of motion describing the dynamic behaviour) of such manipulators with option to include flexibility is therefore needed for adoption in the design and simulation of the control scheme to provide appropriate control of lightweight manipulators at increased speed and heavier payloads. This can be achieved through the description of link flexibility by the finite element with an appropriate selection of the number of elements.

It is evident that the more finite elements adopted, the more accurate the model response can be [4]. However, the fact of reality is, one can not simply take more finite elements. The reason is that the computation of that model will rise sharply with the growth of number of finite elements.
Therefore, as a compromise, a suitable number of finite elements are employed to yield the necessary design tolerance. In many cases, just a few finite elements are found to be sufficient.

1.2 PROBLEM DEFINITION

The dynamic model essentially describes the dynamic characteristics of flexible manipulators. Based on this model, the positions, velocities and accelerations of the manipulator links could be determined by the input parameters dictated by the control system. In other words the dynamic models are to be prescribed in the form [5]

\[ \tau = A(q) \cdot \dot{q} + H(q, \dot{q}) \]  

where

- \( \tau \) is a vector of generalized forces or torques,
- \( q \) is a vector of variables of the system,
- \( A \) is a square mass matrix,
- \( H \) is a coefficient vector including gravity effect etc..

In order to achieve this, various approaches have been developed to conform to such a model. The two main approaches to the dynamic modelling of flexible robot arms are the assumed modes method and the finite element method. The assumed modes method is quite general and contains less
variables and can lead to efficient computation. However, this method requires the precise assumed mode shape for the links and hence limits the use of this method only for manipulators with simple shaped links [6]. The finite element method, however, could be applied to manipulators when links are of non-regular cross-sections and include better accuracy as well [7].

A number of investigations have been carried out employing finite element approach to derive the dynamic equations. However, these equations are restricted to only certain cases. In this thesis, the main contribution involves derivation of the generalized model equations in a finite element setting. This approach is found more suitable for design of robot control.

1.3 PRESENT STATE OF THE DYNAMIC MODELLING THROUGH FINITE ELEMENT

The methods for dynamic modelling of manipulators by means of finite element concept were presented by Gerdin [8] and Bricont [9]. Each flexible link was considered as one element so that the dynamic equations could be derived by the Lagrangian method. Since these methods did not discuss the case of a link with several elements, the accuracy could only be improved by choosing an appropriate mode shape of elements.
Usoro, Nadira and Mahil [10] developed another method to advance the dynamic model based on the finite element approach. With each flexible link of the manipulator being divided into elements, the accuracy of the response was achieved by increasing the number of elements of each flexible link. However, this investigation has application limitations since the dimension of mass matrix of the equations is dependent on the number of elements chosen for each link and the number of links. With the number of links increased and more elements chosen, the mass matrix becomes too bulky to be handled. Therefore, these authors discussed only the case of a two-link manipulator with two elements for each link instead of deriving more generalized equations for design purpose.

Book [11] proposed a method of recursive Lagrangian dynamics for flexible manipulator arms. Here [4x4] matrices are utilized to represent both the joint and deflection motions. The computational approach resulting from the Lagrangian formulation of the system dynamics, that is reduced to recursive form, has already been proven as an efficient method for manipulators with rigid links. To consider the flexibility of robot manipulator, the so called assumed modes method, which assumes the link's deformed shape by a certain describing function, is employed. Since the assumed modes method, where a certain mode shape is presumed for each link, is adopted in this work, this may not be suitable to describe
the manipulators with complex shaped links.

A computer simulation of the control of a flexible robot arm was carried out by Lee and Wang [12]. The dynamic equations for a single-link flexible robot arm were derived in a rigorous manner. The flexible beam is modeled as \( n \) beam elements and \( n+1 \) nodes. As the model employs the Newton and not Lagrangian formulation, it could only be fit for simple manipulator examples. In addition, the calculation of some coefficients grows very rapidly with an increase in the number of links. Here, the moment acting on the beam could not always be considered as zero particularly in case of a multi-link arm. If the moment could not be ignored, it will become difficult to obtain the governing equations using this approach for a flexible manipulator arm.

Based on the above work, Lee and Wang [13] developed the dynamic equations for a two-link flexible robot arm. The main success in this work centres around the determination of the inverse of matrix \( A^* \) which links the acceleration vector with the vector combining velocity variables and position variables. However, the inverse of \( A^* \) can not be easily obtained as well as it is impossible to obtain this quantity for a more general case. With an increase in the number of links, calculations of velocity and acceleration also become extremely complicated.

Chang and Hamilton [14] presented a dynamic model for robot manipulators with flexible links by means of the finite
element method and Lagrange's formulation. In this work, an Equivalent Rigid Link System (ERLS) model was used which describes the kinematics of robot manipulators with flexible links by separating the global motion of the flexible manipulator into large and small motions. This algorithm was suggested to simplify the analysis of the flexible robot arms. However the authors [14] did not consider the case of manipulator links having more than one element. They just considered the equations of links with single element.

Gaultier and Cleghorn [15] use the Hamilton's principle to implement the modelling of both planar and spatial flexible manipulators by creating a beam finite element. The element employs torsional, axial, and lateral shape functions to approximate the link deformation vector. The governing differential equations for an arbitrary spatially translating and rotating flexible link were finally derived. The derivation was restricted only to links which can adopt to Euler-Bernoulli beam theory of constant cross sectional area.

Naganathan and Soni [16] presented a finite, element-based nonlinear model of flexibility effects in certain class of manipulators. The governing equations of motion are derived including the effects of rotary inertia, shear deformation, and effects of nonlinear motion of each of the links. However, a uniform cross section of manipulator links is assumed which limits the application of this method.

It can be realized from the above literature survey that
the various approaches for flexible manipulator modelling by the previous researchers can be classified under 2 major groups:

1. **Use of assumed modes**: This approach is recommended by Book [11], Gordaninejad and Azhdari [17]. However, these researchers offer discussions and applications that are limited only to manipulator links with uniform cross section.

2. **Use of finite element**: This approach is recommended by Geradin [8], Usoro [10], Naganathan and Soni [16], Lee and Wang [12] [13], Bricout [9], Jonker [18], Chang and Hamilton [14] [19]. As mentioned previously, these investigations do not give or lead to a generalized dynamic equations for any type of flexible robot manipulators. References [10] [12] [13] discuss only specific cases with one or, at best, two links. Investigations [8] [14] derived the dynamic equations for flexible manipulators with one element in each link. This certainly reduces the ability of these approaches to obtain a better accuracy of the manipulator response and behaviour which may be needed in certain robotic designs and control. As all the above works are limited to specific manipulators, they cannot be employed for any general type of robot manipulators making use of finite element method. This shortcoming is addressed in this investigation.
1.4 PROFILE OF THE THESIS

The objective of this thesis is to derive a generalized dynamic equation, which can be employed for any flexible robot manipulator with revolute joints. The finite element approach is employed to model any multi-link flexible manipulators. The whole work presented in the following chapters of this thesis may be divided into 3 stages:

The first stage is to analyze the kinematic character of the flexible manipulators by the concept of finite element. Two types of coordinates (body-fixed system of coordinates attached to links and coordinates attached to elements of links) are utilized so that the points on a beam could be expressed in terms of these coordinates systems. Small deflection characteristic is assumed in order to simplify the analysis to linear relationships and so that the general transformation matrix can be easily set up. The adoption of finite element is introduced in the analysis at this stage.

The second stage is to derive the dynamic equations for flexible robot manipulators. As the position of each point on the link could be expressed by means of the transformation matrix, the kinetic energy for each element is computed and summed over all the elements. The potential energy is computed in the same manner as well. Then the Lagrangian formulation is applied to set up the dynamic equations of the system.

In the third stage, the test, by means of computational
simulations, is performed in order to check the validity and correctness of the derived dynamic equations. This is important for algorithm development. Certain initial conditions are applied to the simulation in this test procedure. Since the different manipulators deployed in practice may possess varying characteristics, the choice of shape functions may greatly influence the results. In order to compare the present results with those obtained earlier by other methods, the parameter values of the model used by Usoro[10] are also employed here using the same initial conditions and other additional conditions specified in [10]. The validity of the present approach is thus ascertained by the above process of comparison. However, it may be necessary to validate further the present method with additional examples that involve more links and more finite elements. But, there are no published literature giving details of such examples.

In the second simulation, a one-link manipulator with its link divided into two finite elements is also discussed using the same linkage parameters as those given by Usoro[10]. The Runge-Kutta method is employed to solve the dynamic equations of which all the joints of flexible manipulators are revolute as shown in Fig 1.1. A torque is introduced in such a manner that the application potential of the procedures developed in this thesis could be demonstrated.
Fig. 1.1  Revolute Joints [20]
CHAPTER 2

KINEMATIC ANALYSIS FOR A ROBOT WITH
REVOLUTE TYPE JOINT CONFIGURATION

2.1 INTRODUCTION

Kinematic analysis has been established as the tool to study the spatial configuration of robot as a function of joint angles and other linkage variables. This yields the relationship between the base coordinate system and specified local systems. The transformation from the local coordinate systems to the base system is very important for the proposed analysis as the positions, velocities and accelerations in different systems are to be converted into the same coordinate system which will bring some elegance as well as convenience to the analysis such as computation of system potential energy etc.

2.2 COORDINATE SYSTEM ASSIGNMENT

A manipulator consists of several links connected sequentially by actual joints. Consider the manipulator as described in Fig 2.1, $A_i$ is the joint transformation matrix for joint $i$, $D_{i,j}$ is the link transformation matrix for link $j$ between joints $i-1$ and $i$, $B_j$ is the cumulative transformation matrix from origin of base coordinate to the
Fig. 2.1 Link Relations for Flexible Manipulator
origin of the local coordinate for link \( i \). The following investigations are made under the assumption of straight link and small deflections.

Let the coordinate system \( O_XY_z \) be defined on link \( i \) with the origin of the coordinate system coinciding with joint \( i \) so that the \( x \) axis is coincident with the neutral axis of the link in its undeformed condition. Thus, the position of the points on link \( i \) can be expressed in terms of the coordinate system \( O_XY_z \), which could be understood from Fig.2.2.

Suppose all the manipulator links are made up of many finite elements, the deflection of a spatially defined element can be described in the three directions \( U', V' \) and \( W' \), as shown in Fig.2.3. For each node of finite elements, there are a total of 6 deflections composed of 3 angular deflections (\( U'_1, V'_1, W'_3; U'_4, V'_4, W'_4 \)) and 3 linear deflections (\( U'_5, V'_5, W'_5; U'_6, V'_6, W'_6 \)). These are indicated in the figure for a given element.

2.3 THE KINEMATIC EQUATIONS

Let the following quantities be defined for setting up the kinematic equations of the manipulator links:

\[ r_{ij}(x_{ij}) : \text{the deflection in terms of position variable} \]

\[ x \] of the \( j \)th element of link \( i \) in terms of coordinates \( O_XY_z \), where superscript \( i \) denotes the reference to \( i \)th
Fig. 2.2 Configuration of Local Coordinate System
Fig. 2.3 Nodal Displacements
coordinate system \(O,X,Y,Z\).

\(r_{ij}(x_{ij})\): the deflection in position variable \(x_{ij}\) of the
\(j\)th element of link \(i\) in terms of the base coordinate. The
neglect of superscript denotes reference to the base
coordinate system.

\(T_i^0\): the transformation matrix for operation from base
coordinate system to local system \(O,X,Y,Z\) in terms of base
coordinate.

\(T_i\): the simplified form of \(T_i^0\).

Thus, the instantaneous position of a point in \(j\)th
element on link \(i\) in terms of the base coordinate system is
given as

\[
K_{ij}(x_{ij}) = T_i^0 * r_{ij}^i(x_{ij}) = T_i * r_{ij}^i(x_{ij}) \tag{2.1}
\]

The relationship between \(r_{ij}\) and \(r_{ij}^i\) is also shown in
Fig.2.4. The point expressed in terms of \(i\)th coordinate system
has to be transformed by matrix \(T_i\) into the base coordinate
system.

The transformation matrix from the base coordinate system
to the local system \(O,X,Y,Z\) is expressed as:

\[
T_i = T_{i-1} * D_{i-1} * A_i = B_{i-1} * A_i \tag{2.2}
\]

Therefore, the position of the point in terms of
Fig. 2.4 Basic Nomenclature for Transformation
coordinate $O_0X,Y,Z$, is given as:

$$
\mathbf{r}_{ij}(x_{ij}) = \begin{bmatrix}
(j-1)l_{ij} + x_{ij} \\
0 \\
0 \\
1
\end{bmatrix} + \begin{bmatrix}
\phi^i_{i,jx}(x_{ij}, t) \\
\phi^i_{i,jy}(x_{ij}, t) \\
\phi^i_{i,jz}(x_{ij}, t)
\end{bmatrix}
$$

(2.3)

where

$l_{ij}$: $j$th element length of $i$th link

$x_{ij}$: position of the point in the $j$th element measured from $O_{ij}$, and

$O_{i}, X_i, Y_i, Z_i$: Body-fixed coordinates attached to the $j$th element of link $i$ with $O_{ij}$ fixed to the junction between the $j$th and $(j-1)$th elements.

In the expression for $\mathbf{r}_{ij}(x_{ij})$, the first part describes the position of the point when the link is undeformed and the second part shows the deformation position of the point. The latter part has to be expanded using element property.

The second part of $\mathbf{r}_{ij}(x_{ij})$ can then be described in terms of shape function in the following manner.

$$
\phi^i_{i,jx}(x_{ij}, t) = \sum_{k=1}^{4} N_{ij, k}(x_{ij}) * u_{ijxk}(t)
$$

(2.4a)

$$
\phi^i_{i,jy}(x_{ij}, t) = \sum_{k=1}^{4} N_{ij, k}(x_{ij}) * u_{ijyk}(t)
$$

(2.4b)
\[ \phi_{i,jz}^i(x_{ij}, t) = \sum_{k=1}^{4} N_{i,jz,k}(x_{ij}) \cdot u_{i,jz,k}(t) \] (2.4c)

and

\[ \phi_{i,jp}^i(x_{ij}, t) = \sum_{k=1}^{4} N_{i,jp,k}(x_{ij}) \cdot u_{i,jp,k}(t) \] (2.4d)

where

\[ \phi_{i,jx}^i, \phi_{i,jy}^i, \text{ and } \phi_{i,jz}^i \text{ are the link deflections along } x, y \text{ and } z \text{ axes respectively; } \phi_{i,jp}^i \text{ is the torsional angular displacement; } N_{i,jx,k}, N_{i,jy,k}, \text{ and } N_{i,jz,k} \text{ respectively are the shape functions about the } x, y \text{ and } z \text{ axes and } u_{i,jx}, u_{i,jy}, \text{ and } u_{i,jz} \text{ respectively are finite elements nodal variables about the } x, y \text{ and } z \text{ axes.}

Since the deformation of link causes both translation and rotation of the coordinate system, the link transformation matrix \( D_i \) from joint \( i-1 \) to \( i \) can be obtained in terms of the nodal vector of the last finite element on the link \( i \) and the total number \( n \) of the elements in this link.

\[ D_i = \begin{bmatrix} 1 & 0 & 0 & nI_{ij} \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} + P_i \] (2.5)

The former part of \( D_i \) describes the transformation between

20
along the x axis when link is in its undeformed situation. \( P_i \) is the additional matrix indicating how much elastic deformation the link takes. Since small deflections have been assumed, it can be shown

\[
P_i = \begin{bmatrix}
0 & -u_{ix3} & u_{ix1} & u_{ix4} \\
-u_{iy3} & 0 & -u_{iy1} & u_{iy4} \\
u_{iz3} & u_{iz1} & 0 & u_{iz4} \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

(2.6)

Here \( u_{ix}, u_{iy}, \) and \( u_{iz} \), respectively are the nodal deformation variables which describe the flexural slopes at tip of link \( i \) about axes \( y, z \) and \( x \). \( u_{ix}, u_{iy}, \) and \( u_{iz} \), respectively are the nodal deformation variables which describe the flexural deflections at the tip of link \( i \) along axes \( x, y \) and \( z \).

Taking the time derivative of the expression for the position given by equation (2.1),

\[
\frac{d\mathbf{r}_{ij}(x_{ij})}{dt} = \mathbf{T}_i \cdot \mathbf{r}_{ij}(x_{ij}) + \mathbf{T}_i \cdot \mathbf{r}_{ij}(x_{ij})
\]

(2.7)
The expression for $\dot{t}^i_{ij}$ can be obtained by differentiating equation (2.3). Since the first part of $t^i_{ij}$ is not dependent on time, the differentiation of this part gives zero. Therefore, the result of the differentiation becomes:

$$
\dot{t}^i_{ij}(x_{ij}) = \left[ \sum_{k=1}^{4} N_{i,j,k}(x_{ij}) \cdot \dot{u}_{j,k}(t) \right]
$$

By differentiating (2.2), one can obtain

$$
\ddot{t}_i = \ddot{B}_{i-1} \cdot \dot{A}_i + B_{i-1} \cdot \dot{\dot{A}}_i
$$

and

$$
\ddot{t}_j = \ddot{B}_{j-1} \cdot \dot{A}_j + 2\dot{B}_{j-1} \cdot \dot{\dot{A}}_j + B_{j-1} \cdot \ddot{A}_j
$$

where

$$
\dot{A}_i = \frac{\partial A_i}{\partial \dot{\theta}_i} \cdot \dot{\theta}_i
$$

and
\[ \ddot{A}_i = \frac{\partial^2 A_i}{\partial \theta_i^2} \dot{\theta}_i^2 + \frac{\partial A_i}{\partial \theta_i} \dot{\theta}_i \]  

(2.11b)

Here \( \theta_i \) is the joint variable.

\( B_i \) can be expressed as:

\[ B_i = T_i \cdot D_i \]  

(2.12)

\( \dot{B}_i \) and \( \ddot{B}_i \) can be also computed by performing the differentiation of equation (2.12):

\[ \dot{B}_i = \dot{T}_i \cdot D_i + T_i \cdot \dot{D}_i \]  

(2.13a)

and

\[ \ddot{B}_i = \ddot{T}_i \cdot D_i + 2 \dot{T}_i \cdot \ddot{D}_i + T_i \cdot \dddot{D}_i \]  

(2.13b)

From the expression in equation (2.5), it is easy to obtain the following results:

\[ \ddot{D}_i = \dddot{P}_i \]  

(2.14a)

and
\[
\tilde{D}_i = \tilde{P}_i
\]

(2.14b)

These equations will be applied when the transformation matrices have to be developed for use, especially in the simulation and discussion regarding further extension of this method.
CHAPTER 3

DYNAMIC ANALYSIS AND MODELLING

FOR FLEXIBLE MANIPULATORS

3.1 INTRODUCTION

Based on a kinematic analysis, one can obtain the expression for the manipulator system's kinetic energy and potential energy which are required for use in developing the system Lagrange's equations. The system potential energy comprises two parts: the potential energy due to gravity and the elastic potential energy (or the strain energy). As explained in the previous chapter, all the different element potential energies due to gravity have to be expressed with reference to the unified coordinate system, which is the base coordinate. A summation over all the manipulator elements will provide the total system potential energy due to gravity. The same strategy is used to sum up the elastic potential energy and kinetic energy over all the elements of the system.

After the above procedure, the equations of motion can be derived using Lagrange's principle. The degrees of freedom of the system can be separated into two groups, i.e., the rigid body degrees of freedom and the elastic degrees of freedom.
3.2 THE SYSTEM KINETIC ENERGY AND ITS DERIVATIVES

In order to develop the manipulator finite element formulation in a generalized manner, all the expressions are managed to result in the form of multiplications of \([4 \times 1]\) transformation matrices. The absolute velocity of one point on the element is given by expression (3.7) and it is now possible to develop an expression for the kinetic energy of a point on the \(j\)th element of \(i\)th link

\[
dk_{ij} = \frac{1}{2} \text{Tr}[\dot{\mathbf{x}}_{ij}(x_{ij}) \cdot \mathbf{\dot{x}}_{ij}^T(x_{ij})] \, dm
\]

\[
eq \frac{1}{2} \text{Tr}[\dot{\mathbf{x}}_{ij}(x_{ij}) \cdot \dot{\mathbf{x}}_{ij}^T(x_{ij})] \, \mu dx_{ij} \quad (3.1)
\]

where \(\mu dx_{ij}\) is the differential mass of the point under consideration.

Since \(\text{Tr}(ab^T) = \text{Tr}(ba^T)\) and substituting

\[
\dot{\mathbf{x}}_{ij}(x_{ij}) = \mathbf{T}_i \cdot \dot{\mathbf{x}}_{ij}^T(x_{ij}) + \mathbf{T}_i \cdot \mathbf{\dot{x}}_{ij}^T(x_{ij})
\]

from equation (3.7), the expanded form of equation (3.1) can be written as [11].

\[
dk_{ij} = \frac{1}{2} \mu dx_{ij} \text{Tr}[\dot{T}_i \cdot \mathbf{\dot{\mathbf{x}}}_{ij}^T(x_{ij}) \cdot T_i^T \cdot 2 \dot{T}_i \\
\cdot \mathbf{\dot{\mathbf{x}}}_{ij}^T(x_{ij}) \cdot T_i^T \cdot \mathbf{T}_i \cdot \dot{T}_i \cdot \mathbf{T}_i^T \cdot \mathbf{\dot{\mathbf{x}}}_{ij}^T(x_{ij}) \cdot T_i^T] \quad (3.2)
\]

By integrating the above expression over the entire body, one can obtain the total link kinetic energy. Here, \(\mu \) is the
mass density of the link and the integration limits over \( x \) are from 0 to \( l_{ij} \). Summing over all the \( m \) links, the system total kinetic energy is obtained from:

\[
K = \sum_{i=1}^{m} \sum_{j=1}^{n} \int_{0}^{l_{ij}} dk_{ij}
\]  

where \( n \) is the number of elements in each link. This is under the assumption that each link can be separated into \( n \) equal elements.

Noting that the deflection of a component is a collection of multiplication of shape functions and nodal variables, the expression for it in terms of two matrices multiplication is now introduced:

\[
\Phi_{ij} = U_{ij}^T N_{ij}
\]  

Here \( \Phi_{ij} \) is the deflection vector of the jth element of link i with respect to coordinate system \( O,X,Y,Z \). The superscript i denotes reference to the coordinate system employed and here it is \( O,X,Y,Z \). Further,

\[
\Phi_{ij} = [\phi_{ijx}(x_{ij}, t), \phi_{ijy}(x_{ij}, t), \phi_{ijz}(x_{ij}, t), 0]
\]
\( \mathbf{u}_{ij}^i \) is the nodal variable vector of the \( j \)th element of link \( i \) with respect to coordinate \( O, \mathbf{X}, \mathbf{Y}, \mathbf{Z}, \) the quantities with respect to which are referred by the superscript \( i \). Then,

\[
\mathbf{u}_{ij}^i = [\mathbf{u}_{ijx}^i, \mathbf{u}_{ijy}^i, \mathbf{u}_{ijz}^i]_{1 \times 12} \tag{3.6}
\]

where

\[
\mathbf{u}_{ijx}^i = [\mathbf{u}_{ijx1}^i, \mathbf{u}_{ijx2}^i, \mathbf{u}_{ijx3}^i, \mathbf{u}_{ijx4}^i] \tag{3.7a}
\]

\[
\mathbf{u}_{ijy}^i = [\mathbf{u}_{ijy1}^i, \mathbf{u}_{ijy2}^i, \mathbf{u}_{ijy3}^i, \mathbf{u}_{ijy4}^i] \tag{3.7b}
\]

and

\[
\mathbf{u}_{ijz}^i = [\mathbf{u}_{ijz1}^i, \mathbf{u}_{ijz2}^i, \mathbf{u}_{ijz3}^i, \mathbf{u}_{ijz4}^i] \tag{3.7c}
\]

\( \mathbf{N}_{ij}^T \) is the shape function matrix of the \( j \)th element of link \( i \) and is given by,

\[
\mathbf{N}_{ij} = [\mathbf{N}_{ijx}, \mathbf{N}_{ijy}, \mathbf{N}_{ijz}]_{4 \times 12} \tag{3.7d}
\]
where

\[
N_{ijx} = \begin{bmatrix}
N_{ijx1} & N_{ijx2} & N_{ijx3} & N_{ijx4} \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\end{bmatrix}
\]  \hspace{1cm} (3.9a)

\[
N_{ijy} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
N_{ijy1} & N_{ijy2} & N_{ijy3} & N_{ijy4} \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\end{bmatrix}
\]  \hspace{1cm} (3.9b)

and

\[
N_{ijz} = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
N_{ijz1} & N_{ijz2} & N_{ijz3} & N_{ijz4} \\
0 & 0 & 0 & 0 \\
\end{bmatrix}
\]  \hspace{1cm} (3.9c)

The symbols \(N_{ijx1}, N_{ijx2}, N_{ijx3}, N_{ijx4}, N_{ijy1}, N_{ijy2}, N_{ijy3}, N_{ijy4}, N_{ijz1}, N_{ijz2}, N_{ijz3}, N_{ijz4}\), \(N_{\ldots}, N_{\ldots}\), and \(N_{ijz4}\), are the corresponding coefficients in equation (2.4), the symbol \(u_{i1x1}, u_{i1x2}, u_{i1x3}, u_{i1x4}, u_{i1y1}, u_{i1y2}, u_{\ldots}, u_{\ldots}, u_{i1z1}, u_{i1z2}, u_{i1z3}, u_{i1z4}\), and \(u_{ijz4}\) are the corresponding variables in equation (2.4).

The differentiation of equation (3.4) results in:
\[ \Phi_{ij} = U_{ij}^T N_{ij} \]  \hspace{1cm} (3.10)

Defining \( C_{ij} \) as:

\[ C_{ij} = [x_{ij} + (j-1) l_{ij} \ 0 \ 0 \ 1] \]  \hspace{1cm} (3.11)

then equation (2.3) can be arranged in the form:

\[ r_{ij}^i(x_{ij}) = C_{ij}^T \Phi_{ij}^i = C_{ij}^T N_{ij} U_{ij}^T \]  \hspace{1cm} (3.12)

Similarly, the differentiation of equation (3.12) results in

\[ \dot{r}_{ij}^i(x_{ij}) = N_{ij} \dot{U}_{ij}^T \]  \hspace{1cm} (4.13)

By introducing matrices \( F_{ij}^1, F_{ij}^2, \) and \( F_{ij}^3 \) in the following manner,

\[
\begin{align*}
F_{ij}^1 &= \int_{x_{ij}}^{1_{ij}} r_{ij}^i(x_{ij}) r_{ij}^i(x_{ij}) \mu dx_{ij} = \int_{x_{ij}}^{1_{ij}} \mu (C_{ij}^T + N_{ij} U_{ij}^T) \\
& \hspace{1cm} (C_{ij} + U_{ij}^T N_{ij}) dx_{ij} = \int_{x_{ij}}^{1_{ij}} \mu [C_{ij}^T C_{ij} + C_{ij}^T U_{ij}^T N_{ij}^T + N_{ij} U_{ij}^T C_{ij}^T + N_{ij} U_{ij}^T U_{ij}^T N_{ij}^T] dx_{ij} \\
\end{align*}
\]  \hspace{1cm} (4.14)
\[ F_{i,j} = \int_0^{l_{i,j}} \mathbf{r}_{i,j}(x_{i,j}) \mathbf{t}_{i,j}^T(x_{i,j}) \, dm = \int_0^{l_{i,j}} \mu \left( \mathbf{C}^T_{i,j} + N_{i,j} \mathbf{U}^T_{i,j} \right) \mathbf{U}_{i,j}^T N_{i,j} \, dx_{i,j} \]

\[ = \int_0^{l_{i,j}} \mu \left( \mathbf{C}^T_{i,j} \mathbf{U}_{i,j}^T N_{i,j} + N_{i,j} \mathbf{U}^T_{i,j} \mathbf{U}_{i,j}^T N_{i,j} \right) \, dx_{i,j} \quad (3.15) \]

and

\[ F_{i,j} = \int_0^{l_{i,j}} \mathbf{r}_{i,j}(x_{i,j}) \mathbf{t}_{i,j}^T(x_{i,j}) \, dm = \int_0^{l_{i,j}} \mu N_{i,j} \mathbf{U}_{i,j}^T \mathbf{U}_{i,j}^T N_{i,j} \, dx_{i,j} \quad (3.16) \]

then, equation (3.3) becomes:

\[ K = \frac{1}{2} \sum_{i=1}^{m} \sum_{j=1}^{n} \text{Tr} \left[ \dot{T}_i F_{i,j} \dot{T}_j^T + 2 \ddot{T}_i F_{i,j2} \dot{T}_j^T + \dot{T}_i F_{i,j3} \dot{T}_j^T \right] \quad (3.17) \]

Before constructing the Lagrange's equations, it may be noted that there exists following relations [11]:

\[ \frac{\partial \dot{T}_i}{\partial \dot{\theta}_j} = \frac{\partial T_i}{\partial \theta_j} \quad (3.18) \]

\[ \frac{d}{dt} \left( \frac{\partial \dot{T}_i}{\partial \dot{\theta}_j} \right) = \frac{\partial \ddot{T}_i}{\partial \dot{\theta}_j} \quad (3.19) \]
\[
\frac{\partial T_i}{\partial u_j} = \frac{\partial T_i}{\partial u_j}
\]  
(3.20)

and

\[
\frac{d}{dt} \left( \frac{i T_i}{\delta u_j} \right) = \frac{\partial T_i}{\partial u_j}
\]  
(3.21)

It is also helpful in simplifying the result by noticing that 
\[\text{Tr}(A) = \text{Tr}(A^T)\] 
for any square matrix \(A\).

After some simplification and cancellations of some terms,

like:

\[
\frac{\partial T_j}{\partial \theta_j} = 0
\]  
(3.22)

\[
\frac{\partial T_i}{\partial u_j} = 0
\]  
(3.23)

\[
\frac{\partial T_r}{\partial \phi_j} = 0
\]  
(3.24)
\[ \frac{\partial \mathbf{u}_{ij}^T}{\partial \theta_j} = 0 \]  \hspace{1cm} (3.25)

\[ \frac{\partial \mathbf{u}_{ij}^T}{\partial \dot{u}_j} = 0 \]  \hspace{1cm} (3.26)

the part of Lagrange's equation relative to the system kinetic energy corresponding to the rigid body variables results in

\[ \frac{d}{dt} \frac{\partial K}{\partial \dot{u}_j} - \frac{\partial K}{\partial u_j} = \sum_{i=1}^{m} \sum_{j=1}^{n} \text{Tr} \left[ \frac{\partial \mathbf{T}_i}{\partial \theta_k} \left( F_{ij4} \mathbf{T}_i^T + F_{ij5} \mathbf{T}_i^T + F_{ij6} \mathbf{T}_i^T \right) \right] \]  \hspace{1cm} (3.27)

Here

\[ F_{ij4} = \int_0^{l_{ij}} \mu \left( 2 \mathbf{C}_{ij} \mathbf{u}_{ij} \mathbf{N}_{ij}^T + 2 \mathbf{N}_{ij} \mathbf{u}_{ij}^T \mathbf{u}_{ij} \mathbf{N}_{ij}^T \right) \, dx_{ij} \]  \hspace{1cm} (3.28)

\[ F_{ij5} = F_{ij1} \]  \hspace{1cm} (3.29)

and

\[ F_{ij6} = \int_0^{l_{ij}} \mu \left( \mathbf{C}_{ij} \mathbf{u}_{ij} \mathbf{N}_{ij}^T + \mathbf{N}_{ij} \mathbf{u}_{ij}^T \mathbf{u}_{ij} \mathbf{N}_{ij}^T \right) \, dx_{ij} \]  \hspace{1cm} (3.30)
Similarly, the part of Lagrange's equation corresponding to the elastic body variables is:

\[
\frac{d}{dt} \frac{\partial K}{\partial \dot{u}_k} - \frac{\partial K}{\partial u_k} = \frac{1}{2} \sum_{i=1}^m \sum_{j=1}^n \text{Tr} \left[ 2 \ddot{T}_{ij} F_{ijk} T_i^{\top} + \dot{T}_{ij} F_{ijk} T_i^{\top} + 2 \frac{\partial T_{ij}}{\partial u_k} \left( \ddot{T}_{ij} F_{ijk} - \dot{T}_{ij} F_{ijk} \right) \right] \tag{5.31}
\]

Here

\[
F_{ijk} = \frac{\partial F_{ij}}{\partial u_k} = \int_{0}^{1/j} \mu \left( C_{ij} \frac{\partial \dot{u}_{ij}^{\top} N_{ij}}{\partial u_k} + N_{ij} \dot{u}_{ij}^{\top} \frac{\partial \dot{u}_{ij}^{\top}}{\partial u_k} N_{ij}^{\top} \right) dx_{ij} \tag{5.32}
\]

\[
F_{ijk} = \int_{0}^{1/j} 2 \mu \left( C_{ij} \frac{\partial \ddot{u}_{ij}^{\top} N_{ij}}{\partial u_k} + 2 N_{ij} \ddot{u}_{ij}^{\top} \frac{\partial \ddot{u}_{ij}^{\top}}{\partial u_k} N_{ij}^{\top} + N_{ij} \dot{u}_{ij}^{\top} \frac{\partial \dot{u}_{ij}^{\top}}{\partial u_k} N_{ij}^{\top} \right) dx_{ij} \tag{5.33}
\]

\[
F_{ijk} = \int_{0}^{1/j} \mu \left( C_{ij} \frac{\partial \dot{u}_{ij}^{\top} N_{ij}}{\partial u_k} + N_{ij} \dot{u}_{ij}^{\top} \frac{\partial \dot{u}_{ij}^{\top}}{\partial u_k} N_{ij}^{\top} \right)
- N_{ij} \frac{\partial \dot{u}_{ij}^{\top}}{\partial u_k} C_{ij} - N_{ij} \frac{\partial \dot{u}_{ij}^{\top}}{\partial u_k} \dot{u}_{ij} N_{ij}^{\top} \right) dx_{ij} \tag{5.34}
\]

and

\[
F_{ijk} = \int_{0}^{1/j} \mu N_{ij} \left( \frac{\partial \ddot{u}_{ij}^{\top}}{\partial u_k} N_{ij}^{\top} \frac{\partial \ddot{u}_{ij}^{\top}}{\partial u_k} \dot{u}_{ij} N_{ij}^{\top} + \frac{\partial \ddot{u}_{ij}^{\top}}{\partial u_k} \ddot{u}_{ij} N_{ij}^{\top} + \frac{\partial \ddot{u}_{ij}^{\top}}{\partial u_k} \dot{u}_{ij} N_{ij}^{\top} \right) dx_{ij} \tag{5.35}
\]
As the part of Lagrange's equations with respect to the system kinetic energy has been presented, another part refers to system potential energy is about to be developed to complete the Lagrange's equation.

3.3 THE SYSTEM POTENTIAL ENERGY AND ITS DERIVATIVES

The system's potential energy consists of two parts: the elastic potential energy and the gravitational potential energy.

The strain energy of element $j$ on link $i$ can be written as [26]:

$$
(V_{ij})_v = \frac{1}{2} \int_0^{l_{ij}} \left[ EI_y \left( \frac{\partial^2 \phi_{ijy}}{\partial x_{ij}^2} \right)^2 + EI_z \left( \frac{\partial^2 \phi_{ijz}}{\partial x_{ij}^2} \right)^2 \right] dx_{ij} \\
+ \frac{1}{2} \int_0^{l_{ij}} GJ_x \left( \frac{\partial \phi_{ijx}}{\partial x_{ij}} \right)^2 dx_{ij} + \frac{1}{2} \int_0^{l_{ij}} EA \left( \frac{\partial \phi_{ijx}}{\partial x_{ij}} \right)^2 dx_{ij} \tag{3.36}
$$

where $EA$ and $GJ_x$ are the structural rigidities of the link due to extension and torsion. $EI_y$ and $EI_z$ are the bending stiffness of the link in $y, z$ directions. $l_{ij}$ is a length integration domain and $dx_{ij}$ is a differential length of element. $\phi_{ijx}, \phi_{ijy}$ and $\phi_{ijz}$ are the linear displacements in $x, y, z$ directions and $\phi_{ijx}$ is the twist deflection along $x$ axis.

The gravitational potential energy for element $j$ on link
\[ (V_{ij})_g = \int \mu \mathbf{T}_i \cdot \mathbf{r}_j^j (x_{ij}) \, dx_{ij}, \quad (3.37) \]

The gravitational acceleration \( \mathbf{g} \) is a vector which can have components along \( x, y, z \) directions. If the base coordinate is set such that the \( z \) axis is pointing vertically up from the ground, then
\[ \mathbf{g} = [0, 0, 9.8, 0] \text{ (m/s}^2) \]

Thus, the system potential energy is obtained by summing the potential energy expressed in equation (3.36) and (3.37) over all the elements in the system. That is,
\[ V = \sum_{i=1}^{n} \sum_{j=1}^{n} [(V_{ij})_e + (V_{ij})_g] \quad (3.38) \]

From the expression for the system's potential energy, it is clear that no velocity components have been involved. Hence, the derivatives of the system potential energy with respect to joint velocity variables are zero. That is,
\[ \frac{\partial V}{\partial \mathbf{q}_k} = 0 \quad (3.39) \]

It may be noticed that in the expression for system potential energy, only the gravitational component of potential energy contains rigid body variables. Therefore, the derivatives of the elastic potential energy with respect to...
rigid body variables vanished and the following equation is obtained:

\[
\frac{\partial V}{\partial \theta_k} = \sum_{i=1}^{m} \sum_{j=1}^{n} \int_0^1 \mu g_s \frac{\partial T_i}{\partial \theta_k} x_{ij} \, dx_{ij}
\]

(3.40)

where \( \theta_k \) is the \( k \)th joint variable.

Before evaluating the derivatives of the potential energy with respect to elastic variables, the system's potential energy is rearranged into a more compact form. In order to achieve this, the matrices \( K_x, K_y, K_z, K_p \) are introduced into the following derivations. Let

\[
K_x = EA \int_0^1 \frac{\partial^2 N_{ijx}}{\partial x_{ij}^2} \frac{\partial N_{ijx}}{\partial x_{ij}} \, dx_{ij}
\]

(3.41a)

\[
K_y = ET_y \int_0^1 \frac{\partial^2 N_{ijy}}{\partial x_{ij}^2} \frac{\partial^2 N_{ijy}}{\partial x_{ij}^2} \, dx_{ij}
\]

(3.41b)

\[
K_z = ET_z \int_0^1 \frac{\partial^2 N_{ijz}}{\partial x_{ij}^2} \frac{\partial^2 N_{ijz}}{\partial x_{ij}^2} \, dx_{ij}
\]

(3.41c)

and

\[
K_p = GI_x \int_0^1 \frac{\partial N_{ijp}}{\partial x_{ij}} \frac{\partial N_{ijp}}{\partial x_{ij}} \, dx_{ij}
\]

(3.41d)
As a consequence, the following expressions can now be rewritten:

\[
\frac{1}{2} \int_0^{l_{ij}} E A \left( \frac{\partial \phi_{ij}}{\partial x_{ij}} \right)^2 dx_{ij} = \frac{1}{2} u_{ijx}^4 K_x u_{ijx}^4 
\]  
(3.4.2a)

\[
\frac{1}{2} \int_0^{l_{ij}} E I_y \left( \frac{\partial^2 \phi_{ijy}}{\partial x_{ij}^2} \right)^2 dx_{ij} = \frac{1}{2} u_{ijy}^4 K_y u_{ijy}^4 
\]  
(3.4.2b)

\[
\frac{1}{2} \int_0^{l_{ij}} E I_z \left( \frac{\partial^2 \phi_{ijz}}{\partial x_{ij}^2} \right)^2 dx_{ij} = \frac{1}{2} u_{ijz}^4 K_z u_{ijz}^4 
\]  
(3.4.2c)

and

\[
\frac{1}{2} \int_0^{l_{ij}} G I_x \left( \frac{\partial \phi_{ijb}}{\partial x_{ij}} \right)^2 dx_{ij} = \frac{1}{2} u_{ijb}^4 K_b u_{ijb}^4 
\]  
(3.4.2d)

Let a stiffness matrix \( K' \) be constructed such that

\[
K' = \begin{bmatrix}
K_x & 0 & 0 & 0 \\
0 & K_y & 0 & 0 \\
0 & 0 & K_z & 0 \\
0 & 0 & 0 & K_b 
\end{bmatrix}
\]  
(3.4.4)

Further, let the system's potential energy be rewritten.
in the form

\[ V - \sum_{i=1}^{m} \sum_{j=1}^{n} \left( \int_{0}^{1} \mu [g_x, g_y, g_z, 0] * T_i (G_{ij} + N_{ij} \bar{u}_{ij}^r) dx_{ij} \right) + \frac{1}{2} \]

\[ \times (u_{ijx}^i K_u u_{ijx}^i + u_{ijy}^i K_y u_{ijy}^i + u_{ijz}^i K_z u_{ijz}^i + u_{ijp}^i K_p u_{ijp}^i) \] = \sum_{i=1}^{m} \sum_{j=1}^{n} \left( \int_{0}^{1} \mu [g_x, g_y, g_z, 0] * T_i (G_{ij} + N_{ij} \bar{u}_{ij}^r) dx_{ij} \right) + \frac{1}{2} \bar{u}_{ij}^i K' \bar{u}_{ij}^i \tag{3.44} \]

Then, the differentiation of system's potential energy with respect to an arbitrary elastic variable is given by

\[ \frac{\partial V}{\partial u_k} = \sum_{i=1}^{m} \sum_{j=1}^{n} \left[ \int_{0}^{1} \mu [g_x, g_y, g_z, 0] \left( T_i (G_{ij} + N_{ij} \bar{u}_{ij}^r) \frac{\partial u_{ij}^r}{\partial u_k} \right) + \frac{\partial T_i}{\partial u_k} (G_{ij} + N_{ij} \bar{u}_{ij}^r) \right] dx_{ij} + \bar{u}_{ij}^i K' \frac{\partial \bar{u}_{ij}^i}{\partial u_k} \] \tag{3.45} \]

where

\[ \bar{u}_{ij}^i = [ u_{ijx}^i u_{ijy}^i u_{ijz}^i u_{ijp}^i ] \tag{3.46} \]

With the above, all the required parts for Lagrange's formulation have been prepared, and now the entire Lagrange's equation can be simply obtained by assembling the different expressions derived earlier.
3.4 LAGRANGE'S FORMULATION

As a result of equations (3.27) and (3.40), the Lagrangian equations for rigid body variables are expressed in the form

\[
\frac{d}{dt} \frac{\partial K}{\partial \dot{\theta}_k} - \frac{\partial K}{\partial \theta_k} + \sum_{i=1}^{m} \sum_{j=1}^{n} \left[ \text{Tr} \left[ \frac{\partial T_i}{\partial \theta_k} (F_{ij} \dot{x}_{ij}) \right] + \int_0^1 \mu [g_x, g_y, g_z, 0] \right] \\
\frac{\partial T_i}{\partial \theta_k} x_{ij} (x_{ij}) dx_{ij} = \tau_k, \quad k = 1, \ldots, m \tag{3.47}
\]

The generalized force for manipulator rigid body variables can be recognized according to the different type of joint the manipulator possesses. If the joint is revolute, the generalized force in Lagrange's equation is a torque exerted by the actuator. When the joint is prismatic, the generalized force in Lagrange's equation is the force exerted by the actuator. As mentioned in the earlier chapters, the revolute joint is adopted in this thesis in order to simplify the analysis for application to flexible robot manipulators. Therefore the generalized forces in equation (3.47) are the joint torques. The subscript \( k \) indicates the \( k \)th joint.

From equations (3.31) and (3.45), the dynamic equations corresponding to the elastic variables can be obtained.
there are no external forces or moment exerted on the joints between the finite elements, the generalized force in this equation is zero.

$$\frac{d}{dt} \frac{\partial K}{\partial \dot{u}_i} - \frac{\partial K}{\partial u_k} \cdot \frac{\partial V}{\partial u_k} = \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} \text{Tr}[2 \ddot{T}_i F_{ijk} T_i^T + \ddot{T}_i F_{ij} k T_i^T + \ddot{T}_i F_{ij} T_i^T + 2 \frac{\partial T_i}{\partial u_k} \left( \dot{F}_{ij} - F_{ij} \dot{T}_i \right) T_i^T] + \sum_{i=1}^{n} \sum_{j=1}^{n} \left[ \int_0^{l_{ij}} [\mu g \cdot (T_{ij} N_{ij} \frac{\partial u_{ij}^r}{\partial u_k})] + \frac{\partial T_i}{\partial u_k} (C_{ij}^T + N_{ij} U_{ij}^T) dx_{ij} \frac{\partial u_{ij}^r}{\partial u_k} \right] = 0 \quad (3.48)$$

From these Lagrange’s equations, a flexible robot manipulator with revolute joints can be modelled for any dynamic analysis no matter how many links it possesses. One can also gain the required accuracy by choosing a proper number of finite elements to represent the link flexibility. An ideal procedure would be to solve the partial differential equations representing the distributed parameter all continuous dynamic system by certain numerical method. However, even if such methods are available, they may not be suitable for adoption in a PC based facility. Further, if one has to solve such a continuous system by an approximation to a discrete system with large number of elements, it will again lead to the same type of heavy computational requirements. These make a PC based software difficult to implement. That is why in most manipulator dynamic modelling an
optimal number of discrete elements are employed. This is done here also.

3.5 THE DEVELOPMENT OF FINITE ELEMENT ALGORITHM

Before a robot manipulator system design is carried out, the range of responses of the manipulator links due to certain design input have to be figured out to check if the designed system meets all the expected requirements. Then adjustments to the design can be carried out by varying the values of the system parameters until the system response satisfies the expected performance requirements.

The algorithm that is developed for use in the process of design may be outlined through a flow chart detailed in Fig 3.1. The step by step procedure can be restated as follows:

step 1: The system is initialized by transferring the initial conditions and system parameters to the dynamic modelling and analysis program.

step 2: For each finite element, the quantities $F_i$, $F_{ii}$, $F_{ij}$, $F_{ij}$, $F_{ii}$, $F_{iij}$, $K'$ are obtained through integration and partial differentiation as set out earlier, while $\dot{T_i}$, $\ddot{T_i}$ are gained through differentiation.

step 3: The required expressions for all the elements are assembled as given in equations (3.47) and (3.48).

step 4: The proposed numerical method is employed so that the equations arranged in step 3 are solved.
step 5: If the loop is not ended, it will go to step 2 to repeat the procedure for the response corresponding to the next period.

step 6: When the analysis time has reached the prescribed end time, the program is terminated.

Finite Element Approach
CHAPTER 4

DYNAMIC SIMULATION FOR

FLEXIBLE ROBOT MANIPULATOR VALIDATION

4.1 INTRODUCTION

Before a certain mathematical model can be relied upon in the design process, some procedures must be carried out to check its validity and reliability. A dynamic simulation, which imitates the behaviour of flexible robot manipulator by means of the given mathematical model, is one of these procedures that are often used before experimentation. Therefore, the following simulations will be performed to check the validity of the proposed model.

As the first step, a two-link system hanging freely under gravity is simulated. This is the same example that was used by Usoro [10]. A small initial deflection from its balance or equilibrium position, which corresponds to $\theta_1 = -90$ degrees and $\theta_2 = 5$ degrees is given. The initial conditions and all the parameter values of the model used in this simulation are chosen to be the same as those in the simulation presented by Usoro [10]. The reason is that it will be easy to compare the results between two models with the same parameter values in order to establish the applicability of the procedure developed in this thesis.

As the first simulation described above is discussed
without the presence of any joint torque (as presented by Usoro [10]) in the links, a second simulation, which takes into account joint torque on a one-link system is also examined in order to establish the procedure developed in this thesis for other applications. By these two simulations that can be extended to represent general type of manipulator applications, one can conclude the proposed procedure has merit.

Generally speaking, the primary shape of the response fluctuations in the simulation should be in agreement with that of the real system that was designed. However, some factors from both simulation and design may affect the results. They are:

(i) The dynamic model is set up by finite element method. The different number of finite elements chosen will lead to different magnitudes of accuracy of the response.

(ii) The different numerical integration scheme adopted is another source that could affect the response. In this thesis, the Runge-Kutta method is chosen to solve the dynamic equations due to its self-starting property as pointed out in many applications [21][22]. It is believed that this numerical integration procedure will also give sufficient accuracy to the results.

(iii) In order to implement the control scheme for a real robot system, the control aspects may be designed in terms of engineering and economic viability. Hence, some key factors
influencing manipulator dynamic performance may get neglected.

(iv) The parameter values of the actual system may be slightly different from those used in the design process.

Only through simulations, the correctness and validity of the dynamic model presented in this thesis can be assessed. The real system can then be designed relying on the simulation results presented later in this chapter.

4.2 THE SIMULATION OF TWO-LINK MANIPULATOR

In order to be identical with Usoro's[10] example for comparison purposes, the same two-link flexible robot manipulator is investigated in this simulation. As shown in Fig. 4.1, the first link is initially freely hanging under gravity without any payload at the tip. The properties for the two-link manipulator are listed in Table 4.1 by Usoro[10].

Consider the two-link manipulator as depicted in Fig. 4.2. The manipulator consists of link 1 and link 2 which are divided into two finite elements of equal length 1 for sake of both computational efficiency and response accuracy needed in design applications. In this manner, a total number of 18 variables will be utilized (16 elastic variables and 2 rigid body variables) while planar or two dimensional motion is under discussion. However, by certain simplification procedures, the number of variables for such 2-link devices can be reduced to 10 for efficient computational algorithm

Fig. 4.2 Schematic of a Two-link Flexible Manipulator
development.

In the study of a linkage system as the one shown in Fig. 4.3, the elastic variables at the end of one element should describe the same elastic configuration as those corresponding to the starting point of the following element. Therefore, \( u_z \), \( u_r \) in the Fig. 4.3 could be replaced by \( u_3 \), \( u_4 \). In this simulation, a net number of 10 variables are employed after such simplification steps through elimination of 2 mid-link variables in each link.

Considering the fact that the joint 1 is fixed to the base with link 1 being fixed to joint 1, the joint 1 is constrained to have zero translational displacement and only an angular displacement of \( \theta_1 \) with respect to the axis \( OX \). This constrains elastic variables \( u_1 \), \( u_2 \) to be zero, i.e., \( u_1(t) = 0 \), \( u_2(t) = 0 \). The joint 2 has also the same features. It is constrained to have only the angular displacement of \( \theta_2 \) relative to the first and constrains the elastic variables \( w_1 \), \( w_2 \) of the second link to be zero, i.e., \( w_1(t) = 0 \), \( w_2(t) = 0 \). According to these constraints, \( u_1 \), \( u_2 \), \( u_5 \), \( u_r \) of link 1 and \( w_1 \), \( w_2 \), \( w_3 \), \( w_4 \), \( w_6 \) of link 2 could be eliminated in the simulation without affecting the results.

The transformation matrices \( T_i \), \( D_i \), \( A_j \) given in chapter 2 for the first link in this system take the form:
Fig. 4.3 Finite Element Representation
\[ A_1 = T_1 = \begin{bmatrix} c_1 & -s_1 & 0 & 0 \\ s_1 & c_1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]  

(4.1)

and

\[ D_1 = \begin{bmatrix} 1 & 0 & 0 & 2U_1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} + \begin{bmatrix} 0 & -u_7 & 0 & 0 \\ u_7 & 0 & 0 & u_8 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \]

\[ = \begin{bmatrix} 1 & -u_7 & 0 & 2U_1 \\ u_7 & 1 & 0 & u_8 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]  

(4.2)

The corresponding transformation matrices for link 2 are:

\[ A_2 = \begin{bmatrix} c_2 & -s_2 & 0 & 0 \\ s_2 & c_2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]  

(4.3)

\[ D_2 = \begin{bmatrix} 1 & -w_7 & 0 & 2U_1 \\ w_7 & 1 & 0 & w_8 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]  

(4.4)
and

\[ T_2 = A_1D_1A_2 = \begin{bmatrix} c_1 & -s_1 & 0 & 0 \\ s_1 & c_1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -u_7 & 0 & 0 \\ u_7 & 1 & 0 & u_6 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]

\[ \begin{bmatrix} c_2 & -s_2 & 0 & 0 \\ s_2 & c_2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} t_{11} & t_{12} & 0 & t_{14} \\ t_{21} & t_{22} & 0 & t_{24} \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]  \hspace{1cm} (4.11)

where

\[ t_{11} = c_{12} - s_{12}u_7 \]  \hspace{1cm} (4.11a)

\[ t_{12} = -s_{12} - c_{12}u_7 \]  \hspace{1cm} (4.11b)

\[ t_{14} = 2jc_1 - s_1u_8 \]  \hspace{1cm} (4.11c)

\[ t_{21} = s_{12} + c_{12}u_7 \]  \hspace{1cm} (4.11d)

\[ t_{22} = c_{12} - s_{12}u_7 \]  \hspace{1cm} (4.11e)

In the above equations, the following simplification forms of expressions have been employed:

\[ c_1 = \cos \theta_1 \]  \hspace{1cm} (4.11f)
\[ c_2 = \cos \theta_2 \]  
\[ s_1 = \sin \theta_1 \]  
\[ s_2 = \sin \theta_2 \]  
\[ s_{12} = \sin(\theta_1 + \theta_2) \]  
\[ c_{12} = \cos(\theta_1 + \theta_2) \]  

The first order and second order differentiation of matrix \( T \) are given by:

\[
\dot{T}_1 = \begin{bmatrix}
-s_1 & -c_1 & 0 & 0 \\
-c_1 & -s_1 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]  \hspace{1cm} (4.7a)  

\[
\ddot{T}_1 = \begin{bmatrix}
-c_1 & s_1 & 0 & 0 \\
-s_1 & -c_1 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix} + \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]  \hspace{1cm} (4.8)  

The first order differentiation of matrix \( T \) is:

\[
\dot{T}_2 = \begin{bmatrix}
t'_{11} & t'_{12} & 0 & t'_{14} \\
t'_{21} & t'_{22} & 0 & t'_{24} \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]  \hspace{1cm} (4.9)
where
\[
\begin{align*}
t'_{11} &= (-s_1\dot{\theta}_1 - c_1 u_1 \dot{\theta}_1 - s_1 \dot{u}_1) c_2 - (c_1 - s_1 u_1) s_2 \dot{\theta}_2 \\
&= -\left(\dot{\theta}_1 + \dot{\theta}_2\right) \left[s_1 + u_1 c_1\right] - \dot{u}_1 s_1 \\
\end{align*}
\]

\[
\begin{align*}
t'_{12} &= -c_{12} (\dot{\theta}_1 + \dot{\theta}_2) + s_{12} (\dot{\theta}_1 + \dot{\theta}_2) u_1 - c_{12} \dot{u}_1 \\
&= \dot{\theta}_1 (s_{12} u_1 - c_{12}) + \dot{\theta}_2 (s_{12} u_1 - c_{12}) - c_{12} \dot{u}_1 \\
\end{align*}
\]

\[
\begin{align*}
t'_{14} &= -2l s_1 \dot{\theta}_1 - s_1 \dot{u}_1 - c_1 u_1 \dot{\theta}_1 \\
&= -\dot{\theta}_1 (2l s_1 + c_1 u_1) - s_1 \dot{u}_1 \\
\end{align*}
\]

\[
\begin{align*}
t'_{21} &= c_{12} (\dot{\theta}_1 + \dot{\theta}_2) - s_{12} (\dot{\theta}_1 + \dot{\theta}_2) u_1 + c_{12} \dot{u}_1 \\
&= \dot{\theta}_1 (c_{12} - s_{12} u_1) + \dot{\theta}_2 (c_{12} - s_{12} u_1) + c_{12} \dot{u}_1 \\
\end{align*}
\]

\[
\begin{align*}
t'_{22} &= -s_{12} (\dot{\theta}_1 + \dot{\theta}_2) - c_{12} (\dot{\theta}_1 + \dot{\theta}_2) u_1 - s_{12} \dot{u}_1 \\
&= -\dot{\theta}_1 (s_{12} + c_{12} u_1) - \dot{\theta}_2 (s_{12} + c_{12} u_1) - s_{12} \dot{u}_1 \\
\end{align*}
\]

and

\[
\begin{align*}
t'_{24} &= 2l c_1 \dot{\theta}_1 - s_1 u_1 \dot{\theta}_1 + c_1 \dot{u}_1 \\
&= \dot{\theta}_1 (2l c_1 - s_1 u_1) + c_1 \dot{u}_1 \\
\end{align*}
\]

The second order differentiation of \(T\) is:

\[
\tilde{T}_2 = \begin{bmatrix} 
  t''_{11} & t''_{12} & 0 & t''_{14} \\
  t''_{21} & t''_{22} & 0 & t''_{24} \\
  0 & 0 & 0 & 0 \\
  0 & 0 & 0 & 0 
\end{bmatrix}
\]

\[56\]
\[ t''_{11} = - \left( \dot{\theta}_1 + \dot{\theta}_2 \right) (s_{12} + u_7 c_{12}) - \left( \dot{\theta}_1 + \dot{\theta}_2 \right) (c_{12} s_{12} + \dot{\theta}_2) \]
\[ + \dot{u}_7 c_{12} - s_{12} u_7 (\dot{\theta}_1 + \dot{\theta}_2) \]
\[ - \ddot{u}_7 s_{12} - \ddot{u}_7 c_{12} (\dot{\theta}_1 + \dot{\theta}_2) \]
\[ = \ddot{\theta}_1 (s_{12} + u_7 c_{12}) - \ddot{\theta}_2 (s_{12} + u_7 c_{12}) - \ddot{u}_7 s_{12} \]
\[ - (\dot{\theta}_1 + \dot{\theta}_2)^2 (c_{12} s_{12} + \dot{u}_7 c_{12}) - 2 (\dot{\theta}_1 + \dot{\theta}_2) \ddot{u}_7 c_{12} \]  
(4.18)

\[ t''_{12} = \ddot{\theta}_1 (s_{12} u_7 - c_{12}) + \ddot{\theta}_2 (s_{12} u_7 - c_{12}) \]
\[ + (\dot{\theta}_1 + \dot{\theta}_2) [c_{12} u_7 (\dot{\theta}_1 + \dot{\theta}_2) + s_{12} \ddot{u}_7 + s_{12} (\dot{\theta}_1 + \dot{\theta}_2)] \]
\[ + s_{12} u_7 (\dot{\theta}_1 + \dot{\theta}_2) - c_{12} \ddot{u}_7 \]
\[ = \ddot{\theta}_1 (s_{12} u_7 - c_{12}) + \ddot{\theta}_2 (s_{12} u_7 - c_{12}) - \ddot{u}_7 c_{12} \]
\[ + (\dot{\theta}_1 + \dot{\theta}_2)^2 (c_{12} u_7 + s_{12}) + 2 (\dot{\theta}_1 + \dot{\theta}_2) s_{12} \ddot{u}_7 \]  
(4.19)

\[ t''_{14} = - \ddot{u}_6 s_{14} \ddot{\theta}_1 (2.l c_1 - s_1 u_6) - 2 \ddot{\theta}_1 c_1 \ddot{u}_6 \]  
(4.20)

\[ t''_{21} = \ddot{\theta}_1 (c_{12} - s_{12} u_7) + \ddot{\theta}_2 (c_{12} - s_{12} u_7) \]
\[ + (\dot{\theta}_1 + \dot{\theta}_2) [c_{12} u_7 (\dot{\theta}_1 + \dot{\theta}_2) - s_{12} \ddot{u}_7] \]
\[ + c_{12} u_7 - s_{12} \ddot{u}_7 (\dot{\theta}_1 + \dot{\theta}_2) \]
\[ = \ddot{\theta}_1 (c_{12} - s_{12} u_7) + \ddot{\theta}_2 (c_{12} - s_{12} u_7) \]
\[ + \ddot{u}_7 c_{12} + (\dot{\theta}_1 + \dot{\theta}_2)^2 (-s_{12} - c_{12} u_7) - 2 s_{12} \ddot{u}_7 (\dot{\theta}_1 + \dot{\theta}_2) \]  
(4.21)

\[ t''_{22} = - \ddot{\theta}_1 (s_{12} + c_{12} u_7) + \ddot{\theta}_2 (s_{12} + c_{12} u_7) \]
\[ - (\dot{\theta}_1 + \dot{\theta}_2) [c_{12} (\dot{\theta}_1 + \dot{\theta}_2) - s_{12} \ddot{u}_7 (\dot{\theta}_1 + \dot{\theta}_2) + c_{12} \ddot{u}_7] \]
\[ - s_{12} \ddot{u}_7 - c_{12} \ddot{u}_7 (\dot{\theta}_1 + \dot{\theta}_2) \]
\[ = - \ddot{\theta}_1 (s_{12} + c_{12} u_7) + \ddot{\theta}_2 (s_{12} + c_{12} u_7) \]
\[ - \ddot{u}_7 s_{12} - (\dot{\theta}_1 + \dot{\theta}_2)^2 (c_{12} - s_{12} u_7) - 2 c_{12} \ddot{u}_7 (\dot{\theta}_1 + \dot{\theta}_2) \]  
(4.22)
\[
\tau''_{24} = \ddot{\theta}_1 (2c_1 - s_1 u_6) + \ddot{\theta}_1 (-2s_1 \dot{\theta}_1 c_1 u_6 \dot{\theta}_1 \\
- s_1 u_6) + c_1 \ddot{u}_6 - s_1 \dot{u}_6 \dot{\theta}_1 = \ddot{\theta}_1 (2c_1 \\
- s_1 u_6) + \ddot{u}_6 c_1 - \dot{\theta}_1^2 (2c_1 + c_1 u_6) - 2s_1 \dot{\theta}_1 \dot{u}_6
\]

(1.23)

The Hermitian polynomials are employed for the shape
function \( N_{y_1} \). As the simulation restricts the motion in the
plane \( OXY \), the shape function describing the displacement
along axis \( z \) need not be considered. Since there is no torque
acting about the link, the effect of the torsion about \( x \) axis
is so insignificant compared to that due to bending and
therefore can be neglected. It is also suggested that the
deflection in the axial direction can be considered to be of
little significance in relation to the magnitudes of lateral
deflections [15], stating that there is very little coupling
effect. Hence, an assumption of axial rigidity is employed in
the present simulation. As a result, the shape functions are
now given by:

\[
N_{y_1} = N_1 y_1 = x - 2 \frac{x^2}{l} + \frac{x^3}{l^2}
\]

(1.24a)

\[
N_{y_2} = N_2 y_2 = 1 - 3 \frac{x^2}{l^2} + 2 \frac{x^3}{l^4}
\]

(1.24b)

\[
N_{y_3} = N_3 y_3 = - \frac{x^2}{l} + \frac{x^3}{l^2}
\]

(1.24c)

and

\[
N_{y_4} = N_4 y_4 = 3 \frac{x^2}{l^2} - 2 \frac{x^3}{l^4}
\]

(1.24d)
According to the definition of equation (3.11), the vectors \( \mathbf{c}_{11} \) for element 1 and 2 of link 1 are given respectively by the following:

\[
\mathbf{c}_{11} = [x \ 0 \ 0 \ 1] \quad (4.25)
\]

and

\[
\mathbf{c}_{12} = [x+1 \ 0 \ 0 \ 1] \quad (4.26)
\]

Similarly, the vectors for element 1 and 2 of link 2 are respectively given by following expressions:

\[
\mathbf{c}_{21} = [x \ 0 \ 0 \ 1] \quad (4.27)
\]

and

\[
\mathbf{c}_{22} = [x+1 \ 0 \ 0 \ 1] \quad (4.28)
\]

As mentioned in section 4.2, for element 1 on the first link, \( u, u' \) are zero. So \( \mathbf{r}_{ii}^1 \) becomes:

\[
\mathbf{r}_{ii}^1 = \mathbf{c}_{ii}^T + \mathbf{N}_{ii} \mathbf{u}_{ii}^{T} = [x, N_y u_3 + N_y u_4, 0, 1]^T \quad (4.29)
\]
Let \( u_1, u_2 \) replace \( u, u_r \), then \( r_{12}^1 \) for the element 1 on the first link is:

\[
r_{12}^1 = c_{12}^T + N_{12}u_{12}^{2T} = [x+1, N_yu_3 + N_yu_4 + N_yu_4 + N_yu_4, 0, 1]^T \quad (1.30)
\]

Similar to the link 1, element 1 and element 2 of link 2 have following equations respectively:

\[
r_{21}^1 = c_{21}^T + N_{21}u_{21}^{2T} = [x, N_yw_3 + N_yw_4, 0, 1]^T \quad (1.31)
\]

and

\[
r_{22}^1 = c_{22}^T + N_{22}u_{22}^{2T} = [x+1, N_yw_3 + N_yw_4 + N_yw_4 + N_yw_4, 0, 1]^T \quad (1.32)
\]

Because only simulation of a two-link manipulation is presented, the new symbols have been introduced instead of those in the derivations. The variables \( u \) are the variables of first link and the \( w \) indicates the variables of second link.

Following the strategy developed in equations (3.1) to (3.48), the system's kinetic energy and potential energy can now be obtained. After arranging the Lagrange's equation in the form of equation (1.1), appropriate numerical method is utilized to solve the dynamic equations.
The numerical method used in this simulation is the 4th-order Runge-Kutta method, and the strategy of the method is illustrated in Table 4.2. The Runge-Kutta method of computation is popular since it is self-starting and results in good accuracy [21]. In the method, the second-order differential equation is first reduced to two first-order differential equations. Here a differential equation of the form

\[ \dot{x} = f(x, \dot{x}, t) \]  

is rewritten as first order sets:

\[ \dot{x} = y \]  
\[ \dot{y} = f(x, y, t) \]

and then the computation is performed as described in Table 4.2.

The quantities in Table 4.2 are used in the following recurrence formula [22]:

\[ x_{1+1} = x_1 + \frac{h}{6} [Y_1 + 2Y_2 + 2Y_3 + Y_4] \]  
\[ y_{1+1} = y_1 + \frac{h}{6} [F_1 + 2F_2 + 2F_3 + F_4] \]
Table 4.2 4th order Runge-Kutta method

</tr>
</tbody>
</table>
where \( h \) is step length.

The sampling frequency is chosen according to the system under discussion. When the sampling frequency is smaller than a critical frequency, singularity occurs. At the same time, if the sampling frequency is much larger than the critical frequency, the accumulating errors grow with increasing computational time. Therefore, a proper sampling frequency should be chosen to off-set the above disadvantages and to obtain the correct response of the system. By certain amount of trial and error calculations, starting from larger time steps, the step interval in the program loop of the simulation is chosen as 0.0005 seconds. Under such a sampling rate, a set of plots for positions \( \theta_1, \theta_2, u_3, u_4, u_7, u_8, w_2, w_4, w_7 \) and \( w_8 \) with their velocities \( \dot{\theta}_1, \dot{\theta}_2, \dot{u}_3, \dot{u}_4, \dot{u}_7, \dot{u}_8, \dot{w}_2, \dot{w}_4, \dot{w}_7 \) and \( \dot{w}_8 \) are obtained as illustrated in Fig. 4.4 to 4.23.

From plots of \( \theta_1 \) and \( \theta_2 \), it seems that both of them are undergoing a vibrating or oscillating motion. Both motions do not keep a constant amplitude simply because of the coupling effects between link 1 and link 2.

The flexural responses are featured in the two modes of oscillations are: one being a relatively fast vibration mode with high frequency (result of presence of large stiffness) and the other a relatively slow vibration mode. The slow vibration mode shows the similar oscillation shape as that of corresponding joint deflection. When compared with the results

of Usoro's work [10], all the responses in this simulation coincide with those of Usoro's except for four of them, namely, $u_1$, $u_2$, $u_3$, $u_4$. The differences can be seen from Fig. 4.6 to Fig. 4.9 and in Fig. 4.24, Fig 4.25. Fig. 4.6 to Fig. 4.9 illustrate the responses obtained from the procedures developed in this thesis while Fig. 4.24 and 4.25 shows the corresponding responses given in Usoro's work. Although they are quite different, there is no adequate evidence to judge which is right. However, it may be observed that the shape of slow vibration mode of flexural deflection follows the shape of its corresponding joint deflection (Fig. 4.4, Fig. 4.6 to 4.9). These are already shown in the responses of the second link obtained from this investigation as well as from Usoro's work (Fig. 4.5, Fig. 4.10 to 4.13; Fig. 4.24, Fig. 4.25). Further, Fig. 4.6 to Fig. 4.9 have been obtained for a more generalized unrestricted dynamic model and hence the results presented in the thesis are believed to be valid.

4.3 THE SIMULATION OF ONE-LINK MANIPULATOR WITH TORQUE

In order to check validity of the model developed for the more common case when external torques have to be taken into account and also as well to reassure the applicability and validity of the model, a simple one-link system with revolute base joint is introduced. In this one-link manipulator simulation, the torque is exerted on the first

joint. The joint input torques are shown in Fig. 4.26 and are specified as follows:

\[ \tau = 35 \text{ N}\cdot\text{m}, \quad 0 \leq t < 1s \]  
\[ \tau = -35 \text{ N}\cdot\text{m}, \quad 1 \leq t < 2s \]  
\[ \tau = 0 \text{ N}\cdot\text{m}, \quad t \geq 2s \]  

Other properties for the one-link manipulator are listed in Table 4.3 and are taken from [10]. The initial configuration of the one-link manipulator is also shown in Fig. 4.27.

By using the same shape functions as employed in the two-link manipulator simulation and following the same procedure as mentioned in the first simulation, the system's energy (potential energy and kinetic energy) as well as the dynamic equations for this system can be obtained.

By arranging the dynamic equations into the form of equation (1.1), the following matrices corresponding to those in equation (1.1) are obtained:

\[
A = \begin{bmatrix}
    a_{11} & 0.0417 & -0.0833 & 1.25 & 1.0625 \\
    0.0417 & 0.0119 & -0.0045 & 0 & 0.0387 \\
    -0.0833 & -0.0045 & 0.006 & -0.0387 & -0.0655 \\
    1.25 & 0 & -0.0387 & 1.8571 & 0.3214 \\
    1.0625 & 0.0387 & -0.0655 & 0.3214 & 0.9286
\end{bmatrix}

(4.42e)

\[ h_5 = -\mu \dot{\theta}_1^2 (0.37 l u_6 + 0.0311^2 u_3 - 0.0525 l^2 u_4 + 0.1285 l u_4) \]
\[ + 0.5 \mu g l \cos \theta_1 + EI \left( \frac{12}{13} u_6 - \frac{6}{12} u_3 - \frac{6}{12} u_7 - \frac{12}{13} u_4 \right) \]  

(4.42f)

\[ \tau_1 \] in equation (4.41) is specified in equation set (4.38).

The variables vector \( \mathbf{q} \) is \([\theta_1, u_3, u_4, u_7, u_9]^T\).

With the step of 0.0005 seconds, the simulation is implemented by the Runge-Kutta method computation procedure. The angular displacement of joint 1 is illustrated in Fig. 4.28. The joint angle increases till the time reaches certain point between 1 and 2 seconds. After this setting time, the
Fig. 4.28  The Angular deflection of Joint 1 in the Second Simulation
link performs with a free vibration response under the gravitational force.

Fig. 4.29 to Fig. 4.32 are responses for flexural deflection of the system. Each of the links undergoes 3 distinct periods of vibration response: from 0 to 1 second, the deflections are negative; from 1 to 2 seconds, they rise and most part of the deflection reaches positive values; after 2 seconds, they undergo free vibration. Fig. 4.33 is the angular velocity response of joint 1. This also can be identified in terms of 3 distinct periods: from 0 to 1 second, the velocity increases with the response oscillations; between 1 to 2 seconds, the velocity decreases with oscillations; after 2 seconds, they undergo free vibration with high frequency of oscillations. Fig. 4.34 to Fig. 4.37 are the flexural deflection velocities of link 1. The above mentioned 3 periods corresponding to each plot show a similar shape but with the different amplitude levels. These results are in conformance with the expected behaviour of the revolute jointed manipulator links with torque input, and hence the dynamic model developed can be said to have general application for design of flexible manipulators.

CHAPTER 5
CONCLUSIONS AND FUTURE EXTENSION

5.1 INTRODUCTION

In this chapter, a summary of the work achieved and the limitations in its applications are presented. Further, ideas are given for extension of the present method to obtain more explicit expressions for the system variables. The expected challenges for any future extension of this analysis technique are also presented in this chapter.

5.2 SUMMARY OF THE INVESTIGATION

In this thesis, a generalized dynamic model for flexible robot manipulator is set up by finite element approach. As mentioned earlier, some previous works on dynamic modelling for flexible robot manipulator have been carried out by using finite element modelling. However, all these discussions are restricted to certain number of links or finite elements in each link. In order to develop the application of finite element approach to dynamic modelling of flexible robot manipulators, a more generalized formulation representing the dynamic characteristics of flexible robot manipulator with revolute joints and straight links is presented in this thesis. Unlike those works mentioned earlier, the method
presented in this thesis provides a solution for the dynamic model for a flexible robot manipulator with any number of revolute links and finite elements in each link, although in the simulation examples described here included only manipulators with fewer number of links and a small number of finite elements to simplify computation and for comparison. In order to simplify the derivations without loss of accuracy, small deflection is assumed when the manipulator contains more than one link so that the elements of matrix $\mathbf{F}$ can be linearized.

Through the present study of dynamic modelling of flexible robot manipulator, wherein the model properly describes more closely the real manipulator system, it may be possible to implement a control system as per the design requirement. By considering the torque on each joint as stated in this dynamic model, the position, velocity and acceleration at any location can be obtained. Two examples of simulations are given in this thesis. The first simulation investigates a two-link manipulator system without any torque present at the joints. The responses shown in Fig. 4.4 and 4.5 represent the coupling between two links. Both responses do not maintain a constant amplitude due to the coupling effects between the links.

In the second simulation, one-link revolute joint manipulator is discussed. Here, unlike the first simulation, a torque is exerted at the joint. Because one-link manipulator
is a simple system, it is chosen for the simulation so that the response can be easily understood. The link starts to oscillate under the gravitational force when the torque is relieved.

The work presented in this thesis provides useful information on computer based solution of manipulator dynamic model using Runge-Kutta procedure. The flowchart shown in Fig. 3.1 describes how to simulate the manipulator system. As the transformation matrix are expressed in the recursive form, any transformation matrix can be easily obtained by using equations (2.9) to (2.14). A set of second-order differential equations obtained from dynamic equations (3.47) and (3.48) can be solved by applying appropriate numerical integration. The Runge-Kutta procedure is preferred method in many earlier investigations [7] due to its self-starting property as well as for its reasonable level of accuracy.

5.3 LIMITATION OF PRESENT WORK

Although equations (3.47) and (3.48) represent the general dynamic equation for flexible robot manipulator, they are not arranged into the form as equation (1.1). In equations (3.47) and (3.48), the variables do not explicitly appear. This will bring difficulties to either simulation or control design since it may not be possible to compare the orders of magnitudes of different terms.

106
The challenge in any future extension will be to deal with the problem how to separate the variables from the dynamic equations.

5.4 BRIEF DESCRIPTION OF FUTURE EXTENSION

The work can comprise of two parts. One is the task of separating the joint variables, and another is question of separating the elastic variables.

First of all, the differential translation and rotation should be expressed in terms of the given coordinate frame. That is, given a coordinate frame $A_k$, there will exist the following expressions:

$$A_k + dA_k = A_k \cdot \text{Rot}(d\theta_k) \quad (5.1)$$

where $\text{Rot}(d\theta_k)$ is a transformation relation representing a differential rotation $d\theta_k$ about axis $z$ in the given coordinate frame $A_k$.

Therefore, $dA_k$ can be given as:

$$dA_k = A_k \cdot [\text{Rot}(d\theta_k) - 1] = A_k \cdot \Delta_k \quad (5.2)$$

where

$$\Delta_k = \text{Rot}(d\theta_k) - 1 \quad (5.3)$$
Let

\[ \overline{\Delta}_k = \frac{\Delta_k}{d\theta_k} \quad (5.4) \]

Then the equation (5.2) could be rearranged in the following form:

\[ dA_k = A_k \overline{\Delta}_k d\theta_k \quad (5.5) \]

So the derivative of \( A_k \) with respect to time may be easily obtained:

\[ \frac{dA_k}{dt} = A_k \overline{\Delta}_k \dot{\theta}_k \quad (5.6) \]

The following equation is also obtained based on the previous results:

\[ \frac{d^2A_k}{dt^2} = A_k \overline{\Delta}_k \ddot{\theta}_k + A_k \overline{\Delta}_k \dot{\theta}_k^2 \quad (5.7) \]

From equation (5.1) to (5.7), one may find that the joint variables have been separated from the joint transformation matrix \( \Delta_k \).

As the link transformation matrix has more than one
variable, the differentiation of it is different from what is for joint matrix \( A_k \). By separating the elastic variables from the expression of link transformation matrix \( D_k \), one can have:

\[
D_k = D' + Q_x u_{kx} + Q_y u_{ky} + Q_z u_{kz} + Q_1 u_{k1} + Q_2 u_{k2} + Q_{j} u_{kj}
\]

(5.8)

Here \( D' \) is the first part in equation (2.5), \( u_{x}, u_{y}, u_{z}, u_{kx}, u_{ky}, \) and \( u_{kz} \) are the elastic variables, and \( Q_x, Q_y, Q_z, Q_1, Q_2, \) \( Q_{j} \) are matrices which are defined below.

\[
Q_x = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

(5.9)

\[
Q_y = \begin{bmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

(5.9b)

\[
Q_z = \begin{bmatrix}
0 & -1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\]

(5.9c)
\[ Q_1 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \]  
(5.9d)

\[ Q_2 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \]  
(5.9e)

\[ Q_3 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix} \]  
(5.9f)

Therefore, the differentiation of equation (5.8) becomes:

\[
\dot{D}_k = \frac{dD_k}{dt} = \frac{dp_k}{dt} = Q_x \dot{u}_{kx3} + Q_y \dot{u}_{ky3} + Q_z \dot{u}_{kz3} + Q_1 \dot{u}_{kx4} + Q_2 \dot{u}_{ky4} + Q_3 \dot{u}_{kz4} \quad (5.10)
\]

and

\[
\ddot{D}_k = Q_x \ddot{u}_{kx3} + Q_y \ddot{u}_{ky3} + Q_z \ddot{u}_{kz3} + Q_1 \ddot{u}_{kx4} + Q_2 \ddot{u}_{ky4} + Q_3 \ddot{u}_{kz4} \quad (5.11)
\]

As the variables have been separated from the joint transformation matrix \( A \) and link transformation matrix \( D_k \), the transformation matrix \( T_i \) which is made up of \( A \) and \( D \) could
also be expressed by the separated variables. After substituting $T$, and its differentiations into dynamic equations (3.47) and (3.48), the dynamic equations can be arranged in the form of equation (1.1).

As a result of the above arrangement, the whole dynamic equations will become too massive to be handled. Therefore, further simplification have to be introduced. However, this procedure needs far more work and is beyond the scope of this thesis. Also it can be mentioned that a careful experimental verification of the responses may be required to establish a complete validation of the generalized dynamic modelling attempted in this investigation.

Kinematics and Flexibility in Manipulators", The Int. Journal of Robotics Research, Vol.6, No.1, Spring 1987

APPENDIX

The programs for the two simulations are listed in the following pages. They follow the 4th order Runge-Kutta procedure which already was shown in Table 4.2. The coefficients for variables are obtained from equation (3.47) and (3.48) and arranged in the corresponding matrices as given in equation (1.1). Since the simulations are just for cases of robot manipulators with few members only, all the elements of matrices in equation (1.1) are simply carried out by hand instead of constructing another program. In other words, the listed programs execute the task of solving the differential equations which are in the form of equation (1.1). The initial conditions are also specified in the programs.
