ABSTRACT

NEW FOUNDATION MODELS

Walid Hashem Hadid

Due to the recent development in construction techniques and fabrications of precast concrete units, new foundations modes were proposed. It is believed, that these models will have higher bearing capacity and produce less settlement than the similar conventional ones.

The present study, was limited to the analysis of stress distribution below different models. The result showed a reduction in the vertical, horizontal and shear stresses, within a depth equal to the foundation width up to 20%, 45% and 109%, respectively.
ACKNOWLEDGEMENTS

Sharing science and knowledge is one of the reasons for the continuity of civilization.

I wish to express my sincere gratitude to Professor A.M. Hanna, for his guidance, support and expert advice in this field.

Many thanks go out also to Professors H.B. Poorooshasb and Z. Khalil for their assistance and discussions.

I would like to thank all my friends and especially Mr. Nagie Gergis and Miss Ghislainé Cross for their interest, also Miss Maggie Pierotti for typing this thesis.

My most heartfelt thanks to my family for their consideration and especially to my brother Nohad, for his untiring dedication and unending patience, without whose help and constant support this would not have been possible.

LIST OF SYMBOLS

A : area
a : side length for soil element
α : angle in the x,z-plane
α^n : function of α
B : half width of the foundation
β : angle in x,y-plane
ψ : stress function
C : constant
d : distance
dA : unit area
dα : increment
dβ : increment
ds : increment
E : modulus of elasticity
ε_i : strain in the i direction
F_i : force
γ_0 : unit weight
γ_ijkl : strain in the i,j-plane
K : constant
M : a point where the stresses are analysed
M_i : moment
ν : Poisson's ratio
N : a point where the load is applied
O(x,y,z) : system of coordinates
O(r,θ,z) : system of coordinates
ON : vector
ON,i : the first derivative of vector ON
P : load applied on the foundation
q : point load or line load
q₀ : point load or line load
q₁ : point load or line load
q₂ : point load or line load
R : radius
R₁ : distance
R₂ : distance
S : variable in the x direction
σᵢ : normal stress in the i direction
θ : angle in the x,z-plane
u : elongation
v : elongation
w : elongation
w₁ : deflexion
w₂ : deflexion
X : component of stresses in the x direction
Z : component of stresses in the z direction.

CHAPTER I

INTRODUCTION

The science of foundations started to exist at the end of the nineteenth century, however, due to the recent development of construction techniques and the need for high-rise buildings, alternatives should be considered rather than the conventional flat ones to increase bearing capacity, and to reduce settlements of the foundations.

In the design of foundations two requirements must be satisfied, the allowable load applied by the structure should be equal to ultimate bearing capacity of the soil divided by a safety factor, and second the settlement of the foundation should be within tolerable range by the structure.

After insuring the safety of the structure (in the form of the above-mentioned two requirements), the reduction of the cost is a second goal. This could be achieved by conducting related research which leads to a better understanding of the performance of these foundations, and developing new foundation models to improve such performance.

This investigation is to develop a new type of foundation, which will produce a better uniform stress below the foundation and consequently the settlement.
CHAPTER II

THEORETICAL BACKGROUND

2.1. GENERAL

In this chapter background of the theoretical models is briefly described.

Consider the soil as homogeneous isotropic and linear material, the problem of stresses could be a three-dimensional problem (case of point loading), or two-dimensional problem (case of strip line loading).

The theory of elasticity is used for the purpose of analysis. The stress function will be the solution to the equations of equilibrium with respect to the boundary conditions, and the compatibility equation.

The classical problem of Boussinesq dealing with a normal force applied at the plane boundary of a semi-infinite mass, may be solved by superposing solutions, derived from Kelvin and Boussinesq. The Kelvin solution may be used in studying stresses due to a force applied at a great distance from a boundary, the Boussinesq solution is applicable in the case, where the force acts at the surface. The solution proposed by Melan's (1932) and Mindlin (1936) is applicable for the case, where the load is near the surface.

The inherent complexity in the behavior of soil has led to the development of many idealized models of soil behavior. Winkler's model is one of these models, which assumes that the deflexion of the soil is directly proportional to the load applied.
2.2 EQUILIBRIUM EQUATION'S OF SOIL ELEMENT

2.2.1 In Rectangular Coordinates.

Assume an element M Figure 1 at depth Z, three components stresses are acting on each side of the cube, a normal stress \( \sigma_i \) where \( i=1,\ldots,6 \) two shear stresses \( \sigma_{ij} \) and \( \sigma_{ik} \) where \( j=1,\ldots,6 \) and \( k=1,\ldots,6 \). On two opposite sides there are increments in the stresses.

For equilibrium, the sum of forces and moments in X, Y and Z directions must be equal to zero (see Figure 1), where \( dx \cdot dz, dx \cdot dy \) and \( dy \cdot dz \) are the areas of the sides of the cube.

For \( \Sigma F_x = 0 \)

\[
\sigma_x - (\sigma_x - \frac{\partial \sigma_x}{\partial x} dx) dy dz + (-\tau_{zx} + \tau_x + \frac{\partial \tau_{zx}}{\partial z} dz) dx dy
\]

\[
+ (\tau_{yx} + \frac{\partial \tau_{yx}}{\partial y} dy - \tau_{yx}) dx dz = 0
\]

After simplification, the sum of \( \Sigma F_x = 0 \) yields to

\[
\frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{zx}}{\partial z} + \frac{\partial \tau_{yx}}{\partial y} = 0 \tag{1}
\]

similarly for

\( \Sigma F_y = 0 \)

then
Figure 1. Stress tensor components in rectangular coordinates.

Figure 2. Plane stress components in Cartesian coordinates.
\[
\frac{\partial \tau_y}{\partial y} + \frac{\partial \tau_{xy}}{\partial x} + \frac{\partial \tau_{yz}}{\partial z} = 0
\] (2)

and for \(\Sigma F_z = 0\)

then

\[
\frac{\partial \tau_z}{\partial z} + \frac{\partial \tau_{xz}}{\partial x} + \frac{\partial \tau_{yz}}{\partial y} = \gamma_0
\] (3)

where \(\gamma_0\) is the unit weight of the soil.

In case of the two-dimensional problem (Figure 2) (plane \((x, z)\)), the equations (1, 2 and 3) will be reduced to

\[
\frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{zx}}{\partial z} = 0
\] (1-a)

\[
\frac{\partial \sigma_z}{\partial z} + \frac{\partial \tau_{xz}}{\partial x} = \gamma_0
\] (3-a)

Also the sum of the moment in the \(x\) direction is given by

\[
\Sigma M_x = 0
\] (4)

Thus

\[
(\tau_{zy} + \tau_{yz} + \frac{\partial \tau_{zy}}{\partial z} dz) dx dy \frac{\partial z}{z} = 0
\]

\[
(\tau_{yz} + \frac{\partial \tau_{yz}}{\partial y} dy + \tau_{yz}) dx dz \frac{\partial y}{z} = 0
\]

After simplification

\[
(\frac{\partial \tau_{zy}}{\partial z} dz) - (2\tau_{yz} + \frac{\partial \tau_{yz}}{\partial y} dy) = 0
\]
\[ 2(\tau_{zy} - \tau_{yz}) + \left( \frac{\partial \tau_{zy}}{\partial z} \frac{dz}{dy} - \frac{\partial \tau_{yz}}{\partial y} \right) = 0 \]

when \( dy \) and \( dz \) tend to zero, all terms in the above equation, except \( \tau_{zy} \) and \( \tau_{yz} \), approach zero, and thus

\[ \tau_{zy} - \tau_{yz} = 0 \]

then

\[ \tau_{zy} = \tau_{yz} \quad (4-a) \]

Similarly the sum of the moments in the \( y \) and \( z \) directions

\[ \Sigma M_y = 0 \quad (5) \]

thus

\[ \tau_{zx} = \tau_{xz} \quad (5-a) \]

and

\[ \Sigma M_z = 0 \quad (6) \]

yields

\[ \tau_{yx} = \tau_{xy} \quad (6-a) \]

2.2.2 In Cylindrical Coordinates.

Assume an element \( M \) located at a depth \( Z \) from the ground level at a distance \( r \) from the \( z \) axis, Figures 3 and 4. These Figures show the stresses acting on the element projected in planes \((r,z), (z,r) \) and \((z,z)\).

For equilibrium, the sum of forces and moments in the radial direction \( r \), in the tangential direction \( \theta \), and in \( z \) direction, must be equal to zero.
Figure 3: An element in polar coordinates.
Figure 4: Plane stress in cylindrical coordinates.
Hence, we have

\[
\frac{\partial \sigma_r}{\partial r} + \frac{1}{r} \frac{\partial \tau_{r\theta}}{\partial \theta} + \frac{\partial \tau_{r z}}{\partial z} + \frac{\sigma_r - \sigma_\theta}{r} = 0
\]  

(7)

\[
\frac{\partial \tau_{r z}}{\partial r} + \frac{1}{r} \frac{\partial \tau_{\theta z}}{\partial \theta} + \frac{\partial \sigma_z}{\partial z} + \frac{\tau_{r z}}{r} = 0
\]  

(8)

\[
\frac{\partial \tau_{r \theta}}{\partial r} + \frac{1}{r} \frac{\partial \tau_{\theta \theta}}{\partial \theta} + \frac{\partial \sigma_\theta}{\partial z} + \frac{2 \tau_{r \theta}}{r} = 0
\]  

(9)

In case of plane stress (x, z), polar coordinates (r, \theta) can be used by replacing \theta with \theta in Figure 4-a, the equations of equilibrium become

\[
\frac{\partial \sigma_r}{\partial r} + \frac{1}{r} \frac{\partial \tau_{r \theta}}{\partial \theta} + \frac{\sigma_r - \sigma_\theta}{r} = 0
\]  

(10)

\[
\frac{\partial \tau_{r \theta}}{\partial r} + \frac{1}{r} \frac{\partial \tau_{\theta \theta}}{\partial \theta} + \frac{2 \tau_{r \theta}}{r} = 0
\]  

(11)

2.2.3 Relations between Stresses in Polar and Rectangular Coordinates.

Assume an element abc where the plane bc is parallel to the y axis (see Figure 5). If A is the area of the side bc and \theta is the angle between the normal n and x axis, the areas of the two other sides are A \cos \theta and A \sin \theta.

If we denote by \overline{x} and \overline{z}, the components of the stresses acting on the side bc. The equilibrium in the x and z directions yields

\[
\overline{x} = \sigma_x \cos \theta + \tau_{xz} \sin \theta
\]

\[
\overline{z} = \sigma_x \sin \theta + \tau_{xz} \cos \theta
\]  

(12)
Figure 5: The relationships between plane stresses in rectangular and polar coordinates.
However, the stresses $\sigma_r$ and $\tau_{r\theta}$, can be written as

\[
\sigma_r = \bar{X} \cos \theta + \bar{Z} \sin \theta \\
\tau_{r\theta} = \bar{X} \sin \theta + \bar{Z} \cos \theta
\]  \hspace{1cm} (13)

Substituting equation 12 into equation 13, yields

\[
\sigma_r = \sigma_x \cos^2 \theta + \sigma_z \sin^2 \theta + 2 \tau_{xz} \sin \theta \cos \theta \]  \hspace{1cm} (14)
\[
\tau_{r\theta} = \tau_{xy} (\cos^2 \theta - \sin^2 \theta) + (\sigma_z - \sigma_x) \sin \theta \cos \theta \]  \hspace{1cm} (15)

The same analysis could be used in the $\theta$ direction yielding

\[
\sigma_\theta = \sigma_x \sin^2 \theta + \sigma_z \cos^2 \theta - 2 \tau_{xz} \sin \theta \cos \theta \]  \hspace{1cm} (16)

Similarly, $\sigma_x$, $\sigma_z$ and $\tau_{xz}$ could be expressed in terms of $\sigma_r$, $\sigma_\theta$ and $\tau_{r\theta}$ by

\[
\sigma_x = \sigma_r \cos^2 \theta + \sigma_\theta \sin^2 \theta - 2 \tau_{r\theta} \sin \theta \cos \theta \]  \hspace{1cm} (17)
\[
\sigma_z = \sigma_r \sin^2 \theta + \sigma_\theta \cos^2 \theta + 2 \tau_{r\theta} \sin \theta \cos \theta \]  \hspace{1cm} (18)
\[
\sigma_{xz} = (\sigma_r - \sigma_\theta) \sin \theta \cos \theta + \tau_{r\theta} (\cos^2 \theta - \sin^2 \theta) \]  \hspace{1cm} (19)

2.2.4 Compatibility Equations

Assume a cube element $M$ in a soil mass is subject to a load $F_x$, $F_y$, and $F_z$ (as shown in Figure 6), the coordinates of the center of the element are $x$, $y$, $z$, and the cube has a side $a$.
Figure 6. An element under loading.

Figure 7. Stress-strain graph.
The deformations demonstrated as an elongation in the $x$, $y$, and $z$ directions are $u$, $v$ and $w$, and an angular deformation. The elongation by unit length (strain) $\varepsilon$ are given by the following equations

$$
\varepsilon_x = \frac{\partial u}{\partial x} \quad (20)
$$

$$
\varepsilon_y = \frac{\partial v}{\partial y} \quad (21)
$$

$$
\varepsilon_z = \frac{\partial w}{\partial z} \quad (22)
$$

and the angular deformation (shear strain)

In plane $(x,y)$  \( \gamma_{xy} = \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \quad (23) \)

In plane $(x,z)$  \( \gamma_{xz} = \frac{\partial w}{\partial x} + \frac{\partial v}{\partial z} \quad (24) \)

In plane $(y,z)$  \( \gamma_{yz} = \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \quad (25) \)

when the force $F_z$ is only applied on the cube $M$, then the stress which is a force per unit area, could be written as a function of strain, as

$$
\sigma_z = E\varepsilon_z \quad (25)
$$

where $E$ is modulus of elasticity and is the slope of the linear part of Figure 7, the extension of the element in $x$ and $y$ direction is

$$
\varepsilon_x = -\nu \frac{\sigma_z}{E} \quad (27)
$$

$$
\varepsilon_y = -\nu \frac{\sigma_z}{E} \quad (28)
$$
where $\nu$ is the Poisson's ratio.

If the loads $F_x$ and $F_y$ are applied simultaneously with $F_z$, the superposition of all strains in the same direction, expressed as follows

$$
\varepsilon_x = \frac{1}{E} (\sigma_x - \nu(\sigma_y + \sigma_z))
$$

(29) $$
\varepsilon_y = \frac{1}{E} (\sigma_y - \nu(\sigma_x + \sigma_z))
$$

(30) $$
\varepsilon_z = \frac{1}{E} (\sigma_z - \nu(\sigma_x + \sigma_y))
$$

(31)

In case of a two-dimensional problem (plane $(x, z)$), differentiating equation (20) twice with respect to $z$, similarly differentiating equation (22) twice with respect to $x$, and differentiating equation (24), once with respect to $x$, and once with respect to $z$, leads to the following equation called the condition of compatibility

$$
\frac{\partial^2 \varepsilon_x}{\partial z^2} + \frac{\partial^2 \varepsilon_z}{\partial x^2} - \frac{\partial^2 \gamma_{xz}}{\partial x \partial z} = 0
$$

(32)

Substituting equations (29), (30) and (31) in equation (32) yields to the equation of compatibility

$$
\left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) (\sigma_x \sigma_y)
$$

(33)

2.2.5 The Stress Function

In order to determine the stresses at a given element $M$ in a soil mass, a solution to the differential equations of equilibrium with respect to the compatibility equation and the boundary conditions, can be obtained by using the stress function $\psi$. 
For the case of two-dimensional problem, the equations of equilibrium (1-a), (3-a) and the compatibility equation (33):

\[
\frac{\partial \sigma_z}{\partial z} + \frac{\partial \tau_{xz}}{\partial x} = \gamma_0 \quad \frac{\partial \sigma_z}{\partial x} + \frac{\partial \tau_{xz}}{\partial y} = \gamma_0
\]  

(34)

\[
\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial z^2}\right)(\sigma_x + \sigma_z) = 0
\]

(35)

The stress function \(\psi\) can be the solution of equations (34) and (35), and the stresses \(\sigma_x, \sigma_z, \tau_{xz}\) are given by

\[
\sigma_x = \frac{\partial^2 \psi}{\partial z^2} + \gamma_0 z
\]  

(36)

\[
\sigma_z = \frac{\partial^2 \psi}{\partial x^2} + \gamma_0 z
\]  

(37)

\[
\tau_{xz} = -\frac{\partial^2 \psi}{\partial x \partial z}
\]  

(38)

Substituting the value of stresses \(\sigma_x, \sigma_z\) and \(\tau_{xz}\) equations (36), (37), (38), into equations (29), (30), (31), (32), and the result into equation 32, the following partial differential equation is obtained.

\[
\frac{\partial^4 \psi}{\partial x^4} + \frac{2 \partial^4 \psi}{\partial x^2 \partial z^2} + \frac{\partial^4 \psi}{\partial z^4} = \gamma \frac{\partial^2 \psi}{\partial x^2} = 0
\]  

(39)

where \(\gamma\) is the Laplace operator:

\[
\gamma^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial z^2}
\]  

(39-a)
To obtain the solution in polar coordinates, equation (39) can be used. However, Figure 5 shows

\[ x = r \cos \theta \]  \hspace{1cm} (40-a) \\
\[ z = r \sin \theta \]  \hspace{1cm} (40-b) \\
\[ \theta = \tan^{-1}(\frac{z}{x}) \]  \hspace{1cm} (40-c) \\

thus

\[ \frac{\partial r}{\partial x} = \frac{x}{r} = \sin \theta \]  \hspace{1cm} (41-a) \\
\[ \frac{\partial \theta}{\partial x} = \frac{z}{r^2} = -\frac{\sin \theta}{r} \]  \hspace{1cm} (41-b) \\
\[ \frac{\partial \theta}{\partial z} = \frac{\cos \theta}{r} \]  \hspace{1cm} (41-c) \\

thus

\[ \frac{\partial \psi}{\partial x} = \frac{\partial \psi}{\partial r} \frac{\partial r}{\partial x} + \frac{\partial \psi}{\partial \theta} \frac{\partial \theta}{\partial x} = \cos \theta \frac{\partial \psi}{\partial r} - \frac{\sin \theta}{r} \frac{\partial \psi}{\partial \theta} \]  \hspace{1cm} (42) \\

Repeating the differentiation until the fourth order with respect to \( x \) and \( z \), after substituting in equation (39) the following equation is obtained

\[ \left( \frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} \right) \left( \frac{\partial^2 \psi}{\partial r^2} + \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \theta^2} \right) = \frac{\partial^2 \psi}{\partial z^2} \psi = 0 \]  \hspace{1cm} (43) \\

Solutions to the partial differential equations (39) and (43) are solutions to several problems in foundation, with respect to the compatibility and for various boundary conditions.
2.3 STRESSES IN SOIL DUE TO EXTERNAL LOADS

2.3.1 Geostatic Stress

The vertical geostatic stresses is obtained by integrating equation (3)

\[ \sigma_z = \int_0^Z \frac{\partial^2 x}{\partial x^2} \, dz - \int_0^Z \frac{\partial^2 y}{\partial y^2} \, dz \]

\[ \sigma_z = \int_0^Z \frac{\partial^2 x}{\partial x^2} \, dz - \int_0^Z \frac{\partial^2 y}{\partial y^2} \, dz \]

Equation (44)

If the surface of the soil is horizontal and the external force is equal to zero, and \( \gamma_0 \) is constant, then equation (44) becomes

\[ \sigma_z = \int_0^Z \gamma_0 \, dz = \gamma_0 z \]

Equation (45)

2.3.2 Two-dimensional Problem

In many problems, two-dimensional stress conditions are encountered (case of strip foundation, see Figure 8), the strain in the y direction is zero. From equation (30) \( \varepsilon_y \) is given by

\[ \varepsilon_y = \frac{1}{E} (\sigma_y - \nu(\sigma_x + \sigma_z)) = 0 \]

Thus

\[ \sigma_y = \nu(\sigma_x + \sigma_z) \]

Equation (46)

Consider a concentrated vertical load \( q \) acting on a horizontal plate AB (as shown in Figure 8-a), the thickness of the plate is taken as unity (as shown in Figure 8-b). The distribution of the load along the thickness is uniform.

Any element M at a distance \( r \) from the point of application of the load, is subjected to a simple compression in the radial direction.
Figure 8. Radial distribution of stress as used by "Boussinesq".
The stress components are

\[ \sigma_r = \frac{2a}{\pi} \frac{\cos \theta}{r} \quad (47) \]

\[ \sigma_\theta = \tau_{r\theta} = 0 \quad (48) \]

the boundary condition is satisfied, the sum of vertical stress acting on the element \( r \, d\theta \) is equal to zero (see Figure 8-b).

\[ \int_0^\pi \sigma_r \, r \, \cos \theta \, d\theta = \frac{4q}{\pi} \int_0^\pi \cos^2 \theta \, d\theta = q \quad (49) \]

the equation of compatibility (equation (43)) is also satisfied

\[ \left( \frac{2}{ar^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} \right) \left( \frac{\partial^2 \psi}{\partial r^2} + \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \theta^2} \right) = 0 \]

where

\[ \psi = \frac{a}{\pi} \, r \, \theta \sin \theta \quad (50) \]

In this case the solutions of the equations of equilibrium (7, 8 and 9) are given by

\[ \sigma_r = \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \theta^2} \quad (51) \]

\[ \sigma_\theta = \frac{\partial^2 \psi}{\partial r^2} \quad (52) \]

\[ \tau_{r\theta} = -\frac{\partial}{\partial r} \left( \frac{1}{r} \frac{\partial \psi}{\partial \theta} \right) \quad (53) \]

Substituting equation (50) into equations (51), (52) and (53) yields

\[ \sigma_r = \frac{2a}{\pi r} \cos \theta \quad (54) \]

\[ \sigma_\theta = \tau_{r\theta} = 0 \quad (55) \]
To obtain the stresses in the rectangular coordinates substitute equation (54) and (55) for equations (17), (18) and (19). Replacing \( \sin(\theta) \) by \( \frac{x}{r} \) and \( \cos(\theta) \) by \( \frac{z}{r} \), we get

\[
\sigma_z = \sigma_r \cos^2 \theta = \frac{2q}{\pi} \cos^3 \frac{\theta}{r} = \frac{2q}{\pi} \frac{z^3}{r^4} \tag{56}
\]

\[
\sigma_x = \sigma_r \sin^2 \theta \cos^2 \theta = \frac{2q}{\pi} \sin^2 \frac{\theta}{r} \cos^2 \frac{\theta}{r} = \frac{2q}{\pi} \frac{x^2 z}{r^4} \tag{57}
\]

\[
\tau_{xz} = \sigma_r (\sin \theta \cdot \cos \theta) = \frac{2}{\pi} q \frac{\sin \theta \cos^2 \theta}{r} = \frac{2q}{\pi} \frac{x z^2}{r^4} \tag{58}
\]

2.3.3 Point Loading

The point point loading \( q \) is acting on a surface of a semi-infinite mass along the \( z \) axis (see Figure 9). Referring to the equations of equilibrium ((7), (8) and (9)) in cylindrical coordinates the stress \( (\sigma_r, \sigma_\theta \text{ and } \sigma_\phi) \), and the displacements \( (u, v \text{ and } w) \) respectively in \( x, y, z \) directions are independent of \( \phi \), due to the symmetry. Thus, the strains \( \varepsilon_r, \varepsilon_\theta, \varepsilon_z \text{ and } \gamma_{rz} \) can be written as

\[
\varepsilon_r = \frac{3u}{3r} \tag{59}
\]

\[
\varepsilon_\theta = \frac{u}{r} \tag{60}
\]

\[
\varepsilon_z = \frac{3w}{3z} \tag{61}
\]

\[
\gamma_{rz} = \frac{3u}{3z} + \frac{3w}{3r} \tag{62}
\]
Figure 9. Point load acting on a semi-infinite mass.

Figure 10. Spherical coordinates.
and the equations of equilibrium can be reduced to

\[
\frac{\partial \sigma_r}{\partial r} + \frac{\partial \tau_{rz}}{\partial z} + \frac{\tau_{rz}}{r} = 0
\]

(63)

\[
\frac{\partial \tau_{rz}}{\partial r} + \frac{\partial \sigma_z}{\partial z} + \frac{\tau_{rz}}{r} = 0
\]

(64)

The solution to equation (63) and (64) can be found by introducing the stress function \( \psi \) as follows

\[
\sigma_r = \frac{\partial}{\partial z} \left( \nu \psi \frac{\partial \psi}{\partial r} - \frac{3}{2} \frac{\partial^2 \psi}{\partial r^2} \right)
\]

(65)

\[
\sigma_\theta = \frac{\partial}{\partial z} \left( \nu \psi \frac{\partial \psi}{\partial r} - \frac{1}{r} \frac{\partial \psi}{\partial r} \right)
\]

(66)

\[
\sigma_z = \frac{\partial}{\partial z} \left( (2-\nu) \nu \psi \frac{\partial \psi}{\partial z} - \frac{3}{2} \frac{\partial^2 \psi}{\partial z^2} \right)
\]

(67)

\[
\sigma_{rz} = \frac{\partial}{\partial z} \left( (1-\nu) \nu \psi \frac{\partial \psi}{\partial z} - \frac{3}{2} \frac{\partial^2 \psi}{\partial z^2} \right)
\]

(68)

where the function \( \psi \) should also satisfy the compatibility equation (43)

\[
\left( \frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{3}{2} \frac{\partial^2}{\partial z^2} \right) \left( \frac{\partial^2 \psi}{\partial r^2} + \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{3}{2} \frac{\partial^2 \psi}{\partial z^2} \right) = \nabla^2 \nabla^2 \psi = 0
\]

(43)

To solve equation (43) it is convenient to use spherical coordinates (see Figure 10)

\[
r = R \sin \alpha
\]

(69)

\[
z = R \cos \alpha
\]

After differentiation, the operator \( \nabla^2 \) can be determined as

\[
\frac{\partial^2}{\partial r^2} + \frac{2}{3} \frac{\partial^2}{\partial z^2} = \frac{\partial^2}{\partial r^2} + \frac{1}{R} \frac{\partial}{\partial R} + \frac{1}{R^2} \frac{\partial^2}{\partial \alpha^2}
\]

(70)
\[
\frac{\partial^3 \psi}{\partial R^2 \partial r} + \frac{1}{R^2} \cotg \frac{\alpha}{\partial r} + \frac{1}{R^2} \frac{\partial^2 \psi}{\partial \alpha^2} = 0 \tag{72}
\]

A particular solution of equation (72), which is a form of Laplace equation, can be a polynomial of the form:

\[
\psi_n = R^n \cdot \alpha_n \tag{73}
\]

where \( \alpha \) is the angle (ZOM) (see Figure 10).

To find the stresses due to a point loading in a mass, assume the load is acting at the center of a sphere (see Figure 11), due to the fact that some or all of the stresses have singularities, the function \( \psi_n \) will be:

\[
\psi_n = \frac{\alpha_n}{R^{n-2}} \tag{74}
\]

Substituting equation (74) in equation (72), and resolving the equation as Legendre's equation:

\[
\psi_n = \frac{K}{R^{n-2}} \tag{75}
\]

where \( K \) depends on the boundary conditions.

In order to find the stress components in cylindrical coordinates, substituting equation (75) in equations (65), (66), (67) and (68) the following equations are obtained:

\[
\sigma_r = K \left\{ \frac{(1-2\nu)z}{R^3} - \frac{3r^2z}{R^5} \right\} \tag{76}
\]
Figure 11. Point load acting at the center of the sphere.
\[ \sigma_R = \frac{K (1 - 2\nu)}{R^3} \left( \frac{Z}{R^3} - \frac{3z^2}{R^5} \right) \]  

(77)

\[ \sigma_z = -\frac{K (1 - 2\nu)}{R^3} \left( \frac{Z}{R^3} + \frac{3z^2}{R^5} \right) \]  

(78)

\[ \tau_{rz} = -\frac{K (1 - 2\nu)}{R^3} \left( \frac{r z}{R^3} + \frac{3r z^2}{R^5} \right) \]  

(79)

where

\[ R = (r^2 + z^2)^{1/2} \]

In case of a point loading at a given depth, consider the point as a small spherical cavity. Figure 11, the vertical stress \( \sigma_z \) with respect to the boundary conditions is given by the following equation

\[ \tau_{rz} = \sigma_z \sin \alpha + \sigma_R \cos \alpha \]  

(80)

Substituting equations (69), (78) and (79) in equation (80) yields

\[ \tau_{rz} = \frac{K (1 - 2\nu)}{R^2} + \frac{3z^2}{R^4} \]  

(81)

The result of these forces over the surface of the cavity is equal to the force applied \( q \) integrating from \(-\frac{\pi}{2}\) to \(\frac{\pi}{2}\)

\[ \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} r 2\pi r \, d\psi = 2\pi \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} q \]  

thus

\[ K = \frac{q}{8\pi (1 - \nu)} \]  

(82)

Substituting equation (82) in equations (76), (77), (78) and (79), the solution of Kelvin is obtained.

The radial stress \( \sigma_R \) (see Figure 12) can be written as a function of the stress components represented in equations (76), (78) and (79).
Figure 12. Uniform pressure on the sphere represented by a load acting in the $r, z$ direction and in the axis normal to plane $(r, z)$. 
\[ \sigma_R = \sigma_R \sin^2 \alpha + \sigma_z \cos^2 \alpha + 2 \tau_{rz} \sin \alpha \cos \alpha \]

\[ \sigma_R = \frac{-2(1+\nu)}{R^3} \frac{C}{\sin^2 \alpha} + \frac{2(1-\nu)}{(1+\nu) \cos^2 \alpha} \]

where \( C \) is a constant. \( ^{3} \)

If the load \( q \) is applied in the \( r \) direction, the \( \sin \alpha \) will be replaced by \( \cos \alpha \), and hence equation (83) will be

\[ \sigma_R = \frac{-2(1+\nu)}{R^3} \frac{C}{\cos^2 \alpha} + \frac{2(1-\nu)}{1+\nu} \sin^2 \alpha \] \( \text{(84)} \)

If the load \( q \) is applied in the direction perpendicular to the plane \( \theta, r \) the angle \( \alpha \) will be equal to \( \frac{\pi}{2} \), and equation (83) becomes

\[ \sigma_R = \frac{-2(1+\nu)C}{R^3} \] \( \text{(85)} \)

Adding equations (83), (84) and (85) to obtain the radial stress, \( \sigma_r \) in a sphere under load \( P \)

\[ \sigma_R = \frac{-4(1-2\nu)C}{R^3} \] \( \text{(86)} \)

The tangential stress component \( \sigma_t \) can be obtained from the equation of equilibrium, in the spherical coordinates from Figure 12.

\[ \sigma_t = \frac{d\sigma_R}{dR} \frac{R}{2} + \sigma_R \frac{\sigma_R}{R^2} \] \( \text{(87)} \)

Substituting equation (86) in equation (87), yields

\[ \sigma_t = -\frac{1}{2} \frac{C}{R^3} \] \( \text{(88)} \)

The stress components \( \sigma_R, \sigma_z, \tau_3 \) and \( \tau_{rz} \) (in cylindrical coordinates) can be written in functions of \( \sigma_R \) and \( \sigma_t \) by
\[
\sigma_r = \sigma_R \sin^2 \alpha + \sigma_z \cos^2 \alpha = C \frac{\left(\frac{1}{2} r^2 - \frac{1}{2} z^2\right) / (r^2 + z^2)^{5/2}}{r^2 + z^2} \quad (89)
\]

\[
\sigma_z = \sigma_R \cos^2 \alpha + \sigma_t \sin^2 \alpha = C \frac{\left(\frac{1}{2} r^2 - \frac{1}{2} z^2\right) / (r^2 + z^2)^{5/2}}{r^2 + z^2} \quad (90)
\]

\[
\tau_{rz} = \frac{1}{2} \left(\sigma_r - \sigma_z\right) \sin 2\alpha = \frac{3}{2} C \frac{rz}{(r^2 + z^2)^{5/2}} \quad (91)
\]

\[
\sigma_\theta = \sigma_t = -\frac{1}{2} C \frac{\sqrt{2}}{R^3} = -\frac{1}{2} C \frac{\sqrt{2}}{(r^2 + z^2)^{3/2}} \quad (92)
\]

Assume that centers of pressure are uniformly distributed along the z axis from z = 0 to z = +\(\infty\). Then by superposition, the stress components produced in an indefinitely extended solid, are from equations (89), (90), (91) and (92) with a new constant C.

\[
\sigma_r = \frac{C}{2} \left[ \frac{1}{r^2} - \frac{z}{r^2 R} - \frac{z^2}{R^3} \right] \quad (93)
\]

\[
\sigma_z = \frac{C}{2} \left[ \frac{z}{R^3} \right] \quad (94)
\]

\[
\tau_{rz} = \frac{C}{2} \frac{r}{R^3} \quad (95)
\]

\[
\sigma_\theta = -\frac{C}{2} \left[ \frac{1}{r^2} - \frac{z}{r^2 R} \right] \quad (96)
\]

on the z = 0, where the load q is applied. The stresses should satisfy the boundary conditions. The shear stress \(\tau_{rz}\) given by equations (79) and (95) can be determined as

\[
(\tau_{rz})_{z=0} = \frac{K}{r^2} (1 - 2v) \quad (97)
\]

\[
(\tau_{rz})_{z=0} = \frac{1}{2} \frac{C}{r^2} \quad (98)
\]
from equations (97) and (98), the relationship between C and K is given by

$$ C = 2K(1-2\nu) $$

(99)

the second condition for the boundary conditions is: the sum of the vertical stress is equal to \( \theta \), if \( \tilde{z} \) is the vertical component at the boundary

$$ \tilde{z} = \sigma_z \cos \alpha + \tau_{rz} \sin \alpha = 3K \frac{z}{r^4} $$

(100)

integrating \( \tilde{z} \) from \( -\frac{\pi}{2} \) to \( \frac{\pi}{2} \) yields

$$ \phi = r^{\pi/2} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \tilde{z} r(r^2+z^2)^{1/2} \, d\psi = 2 \pi \frac{q}{K} $$

then

$$ K = \frac{q}{2\pi} $$

(101)

thus, from equations (99) and (101), we have

$$ C = \frac{q}{\pi} (1-2\nu) $$

(102)

Finally, substituting the values of K and C in equations (76), (77), (78) and (79), and in equations (93), (94), (95) and (96) respectively, and adding separately for each stress component, the final equations for stresses due to point loading are

$$ \sigma_r = -\frac{q}{2\pi R^2} (1-2\nu) \left( \frac{1}{r^2} - \frac{z}{r^2R} - \frac{3r^2z}{R^5} \right) $$

(103)

$$ \sigma_z = \frac{3q z^3}{2\pi R^5} $$

(104)

$$ \sigma_\theta = -\frac{q}{2} (1-2\nu) \left( \frac{1}{r^2} + \frac{z}{r^2R} + \frac{z}{R^3} \right) $$

(105)
\[ \tau_{rz} = \frac{3q}{2\pi} \frac{rz^2}{R^5} \]  

Substituting equation equation (103), -(106) in equations (17), (18), and (19), the stress components in rectangular coordinates are obtained.

\[ \sigma_x = \frac{3q}{2\pi} \left( \frac{x^2z}{R^5} + \frac{(1-2\nu)}{3} \left( \frac{1}{R(R+z)} - \frac{(2R+z)x^2}{R^3(R+z)^2} - \frac{z^2}{R^3} \right) \right) \tag{107} \]

\[ \sigma_z = \frac{3q}{2\pi} \frac{z^3}{R^5} \tag{103} \]

\[ \tau_{xz} = \frac{3q}{2\pi} \frac{xz^2}{R^5} \tag{109} \]

By replacing \( y \) by \( k \) the stress components \( \sigma_y \) and \( \tau_{yz} \) are obtained.

2.3.4 The Case of a Vertical Line Loading Acting Beneath the Semi-infinite Mass

The line loading \( q \) is acting at depth \( d \) from the surface. To find the stresses acting on an element at depth \( z \), Melan, 1932, developed the following formulas

\[ \sigma_x = -\frac{q}{\pi} \left[ \frac{1}{2(1-\nu)} \left( \frac{(z-d)x^2}{R_1^4} + \frac{(z+d)(x^2+2d^2)-2dx^2}{R_2^4} \right) \right. \]

\[ \left. + \frac{8dzx^2(d+z)}{R_2^6} \right] + \frac{(1-2\nu)}{4(1-\nu)} \left( \frac{z-d}{R_1^2} + \frac{z+3d}{R_2^2} + \frac{4zx^2}{R_2^4} \right) \right] \tag{110} \]

\[ \sigma_z = \frac{q}{\pi} \left[ \frac{1}{2(1-\nu)} \left( \frac{(z-d)^3}{R_1^4} + \frac{(z+d)((z+d)^2+2dz)}{R_2^4} \right) \right. \]

\[ \left. - \frac{8dzx^2(d+z)}{R_2^6} \right] + \frac{1-2\nu}{4(1-\nu)} \left( \frac{(z-d)^2}{R_1^2} + \frac{3z+d}{R_2^2} + \frac{4zx^2}{R_2^4} \right) \tag{111} \]
Figure 13: Vertical line loading beneath the surface of semi-infinite mass.
\[ \tau_{xz} = \frac{q x}{\pi} \left[ \frac{1}{2(1-\nu)} \left( \frac{(2-d)}{R_1^4} + \frac{z^2 - 2dz - d^2}{R_2^4} + \frac{8dz(d+z)^2}{R_2^6} \right) \right] \\
+ \frac{1-2\nu}{4(1-\nu)} \left( \frac{1}{R_1^2} - \frac{1}{R_2^2} + \frac{4z(d+z)}{R_2^4} \right) \]  

(112)

Assume \( \phi = 0 \) then equations (110), (111) and (112) reduce to the equations developed by Boussinesq for a strip loading represented by

\[ \sigma_x = \frac{2q x^2 z}{\pi R_1^4} \]  

(113)

\[ \sigma_z = \frac{2q z^3}{\pi R_1^4} \]  

(114)

\[ \tau_{xz} = \frac{2q z x^2}{\pi R_1^4} \]  

(115)

as there is no deformation in the y direction the horizontal stress components are given by equation (46) as follows

\[ \sigma_y = \nu(\sigma_x + \sigma_z) = \frac{2q v z}{\pi R_2^2} \]  

(116)

2.3.5 In Case of Vertical Point Load Acting Beneath the Surface of a Semi-infinite Mass

If the point load q is acting at depth d (as shown in Figure 14), the stress components at point M located at depth z, are given by (Mindlin, 1936).
Figure 14. Vertical concentrated load beneath the surface of the soil.
\[ \sigma_x = \frac{-q}{8\pi(1-\nu)} \left[ \frac{(1-2\nu)(z-d)}{R_1^3} + \frac{3x^2(z-d)}{R_1^5} + \frac{(1-2\nu)(3(z-d) + 4\nu(z+d))}{R_2^3} \right] \]

\[ \frac{3(3-4\nu)x^2(2-d) - 6d(z+d)(1-2\nu)z - 2vd}{R_2^5} \]

\[ \frac{-30d}{R_2^7} \left[ \frac{x^2(z+d)}{R_2^3} \right] \left( 1 - \frac{x^2}{R_2^2} \right) \]

R_1 and R_2 are shown in Figure 14. Due to the symmetry in the plane x, y, \( X = Y \) then \( \sigma_x = \sigma_y \)

\[ \sigma_z = \frac{-q}{8\pi(1-\nu)} \left[ \frac{(1-2\nu)(z-d)}{R_1^3} + \frac{(1-2\nu)(z-d)}{R_2^3} - \frac{3(z-d)^3}{R_1^5} \right] \]

\[ \frac{3(3-4\nu)z(z+d) - 3d(z+d)(5z-d) - 30dz(z+d)^3}{R_2^7} \]

\[ \tau_{xz} = \frac{-qx}{8\pi(1-\nu)} \left[ \frac{(1-2\nu) + 1-2\nu}{R_1^3} - \frac{3(z-d)^3}{R_1^5} \right] \]

\[ \frac{3(3-4\nu)z(z+d) - 3d(3z+d) - 30dz(z+d)^3}{R_2^7} \]

\( \tau_{yz} = \tau_{xz} \) by replacing \( x \) by \( y \).

If we assume \( d = 0 \) (i.e., the load is acting on the surface), the equations (117), (118) and (119) are equal to equations (107), (108) and (109) derived by Boussinesq.
2.4 WINKLER MODEL OR SOIL BEHAVIOUR.

The application of an external force system to a soil element induces deformation; and if the soil elements behave as a purely elastic material, the resulting displacement is given by a linear function.

A soil model proposed by Winkler (1867), assumes that the deflexion \( w \) in the \( z \) direction is directly proportional to the stress \( q_0 \) and independent of stress levels at other locations (see Figure 15), i.e.,

\[
q_0(x,y) = k_1 w(x,y). \tag{120}
\]

where \( k \) represents the modulus of subgrade reaction with units of stress per unit length.

Physically, Winkler's idealization of the soil medium consists of a system of mutually independent spring elements with stiffness, constants \( k \).

Consider a cylindrical shape as a footing (see Figure 16) for loads \( q_0 \), applied on the soil located between two parallel surfaces \( AB \) and \( MN \).

The cylindrical shape is divided into elements \( ds \), every element is represented as an infinitesimal area of unit length and a width \( ds \), the stress \( q_0 \) for element \( I \) can be also written as

\[
q_I = E \cdot \varepsilon = E \frac{w_I(x,y)}{L} \tag{121}
\]

where \( L \) is the thickness of the soil under the element to the surface \( MN \).
Figure 15. Surface displacement of the Winkler model due to non-uniform load.
Figure 16. Surface displacement under a cylindrical rigid footing, using Winkler model.
If $L + dz$ is the thickness of the soil under the element 2 next to element 1, then

$$q_2 = E \frac{w_2(x,y)}{L + dz} \quad (122)$$

Since the cylindrical footing is assumed as a rigid surface, it will settle uniformly by the amount

$$w(x,y) = w_1(x,y) = w_2(x,y) \quad (123)$$

When the surface MN is at infinity, the thickness $L + dz$ will be equal to L, thus,

$$q_0 = q_1 = q_2$$

Therefore, the vertical loads $q$ applied by the cylindrical surface (footing) is constant.
CHAPTER III.

ANALYSIS OF NEW MODELS

3.1 GENERAL

The concept of a "line loading" can be represented with a load acting on an infinitesimal strip of width ds, while a point loading can be represented with a load acting on an infinitesimal area dA.

In the design of "footing", the structural characteristics of a footing varies with the variation of the shape, also, the intensity and the shape of the load transmitted by the footing to the soil depends on the footing.

In analysing the geometric shape of a footing, the technique of vector analysis is used to compute the infinitesimal area of the footing with a complex shape, i.e., cylindrical, triangular, spherical, etc.

3.2 GENERAL DEFINITION OF A SURFACE

Figure 17, shows a general surface $S_0$ in 0 the $O(x, y, z)$ system. A curve on the surface, or the surface itself can be defined by a vector $\overrightarrow{ON}$ as follows

$$\overrightarrow{ON} = (x, y, z)$$

where $x, y, z$ are the rectangular coordinates, which can be represented by the parameters $\alpha, \beta$ and $\rho$ in the polar system of coordinates.

Where $\alpha$ and $\beta$ are two angles (shown in Figure 19), and $\rho$ is the modulus of $|\overrightarrow{ON}| = \rho$. A footing is a rigid or elastic solid defined by an average surface (see Figure 18), and a thickness 'h' land on a soil (clay,
Figure 17. A surface in triaxial system $O_1(X,Y,Z)$. 
Figure 18. An element of a footing surface.

Figure 19. An infinitesimal unit area dA.
sand, etc.) and support a charge \( P \) from the structure, the charge \( P \) is transmitted to the soil by a unit charge

\[
q = \frac{P}{S_b}
\]

Consider the vector where

\[
\begin{align*}
\overrightarrow{ON} &= (x(\alpha, \beta), y(\alpha, \beta), z(\alpha, \beta)) \\
\end{align*}
\] (125)

taking \( \beta \) as a constant parameter and keeping \( \alpha \) as a variable. The first derivative of \( \overrightarrow{ON} \) is a vector tangent to the surface and directed to the positive direction of \( \alpha \)

\[
\overrightarrow{ON},\alpha = \frac{\overrightarrow{ON}(\alpha + d\alpha, \beta) - \overrightarrow{ON}(\alpha, \beta)}{d\alpha} = \frac{d}{d\alpha} \overrightarrow{ON}(\alpha)
\] (126)

for the increment \( d\alpha \) the point \( N \) moves to a new position \( N_1 \) (see Figure 19).

Similarly taking \( \alpha \) as a constant and keeping \( \beta \) as a variable, the following is obtained

\[
\overrightarrow{ON},\beta = \frac{\overrightarrow{ON}(\alpha, \beta + d\beta) - \overrightarrow{ON}(\alpha, \beta)}{d\beta} = \frac{d}{d\beta} \overrightarrow{ON}(\beta)
\] (127)

and for the increment \( d\beta \) the point \( N \) moves to \( N_2 \).

From equations (126) and (127), the vectors \( N\overrightarrow{N_1} \) and \( N\overrightarrow{N_2} \) can be obtained as

\[
\begin{align*}
N\overrightarrow{N_1} &= d(\overrightarrow{ON}(\alpha)) = \overrightarrow{ON},\alpha \ d\alpha \\
N\overrightarrow{N_2} &= d(\overrightarrow{ON}(\beta)) = \overrightarrow{ON},\beta \ d\beta
\end{align*}
\] (128) (129)

therefore, the area \( dA \) represented by the parallelogram \( N\overrightarrow{N_1}N_2N_3 \) (see Figure 19) is obtained as

\[
dA = |N\overrightarrow{N_1} \times N\overrightarrow{N_2}| = |\overrightarrow{ON},\alpha \times \overrightarrow{ON},\beta| \ d\alpha \ d\beta
\]

\[
= |\overrightarrow{ON},\alpha| \ |\overrightarrow{ON},\beta| \ d\alpha \ d\beta \ \sin \alpha
\] (130)
where \( \omega \) is the angle between the two vectors \( \text{ON}_\alpha \) and \( \text{ON}_\beta \).

The vectors \( \text{ON}_\alpha \) and \( \text{ON}_\beta \) can be represented in the following forms, also

\[
\text{ON}_\alpha = (x_\alpha, y_\alpha, z_\alpha)
\]

and

\[
\text{ON}_\beta = (x_\beta, y_\beta, z_\beta)
\]

thus

\[
|\text{ON}_\alpha|^2 = (x_\alpha^2 + y_\alpha^2 + z_\alpha^2)
\]

and

\[
|\text{ON}_\beta|^2 = (x_\beta^2 + y_\beta^2 + z_\beta^2)
\]

(131)

3.3 CIRCULAR FOOTING

The footing is a circle \((0, \beta)\) of radius \(B\), the point \(M\) is at depth \(z\), and distance \(r\) from the center \(z\) point. The vertical load \(q\) applied at point \(N\) at a distance \(r\) from the center \(O\) of the circle, and an angle \(\beta\).

Then

\[
\text{ON}(x, y) = (r \cos \beta, r \sin \beta)
\]

(132)

\[
\text{ON}_\beta = (-r \sin \beta, r \cos \beta)
\]

(133)

substituting equation (133) in equation (130), yields

\[
dA = |\text{ON}_\beta| |\text{ON}_\alpha| \, d\beta \, dr \, \sin \omega
\]

however, \(\text{ON}_\beta\) and \(\text{ON}_\alpha\) are two orthogonal vectors.
Figure 20. Figure showing the vectors and stresses analysis for a circular flat footing.
\[ \mathbf{ON}_\beta \cdot \mathbf{ON}_r = -r \cos \beta \sin \beta + r \cos \beta \sin \beta = 0 \]

then \( \sin \omega = 1 \) and

\[ dA = |\mathbf{ON}_\beta| |\mathbf{ON}_r| \, d\theta dr = \left( r^2 \sin^2 \beta + r^2 \cos^2 \beta \right)^{1/2} \]

\[ = (\sin^2 \beta + \cos^2 \beta)^{1/2} = rd\theta dr \]

therefore

\[ dA = rd\theta dr \quad (135) \]

If \( P \) is the load applied on the circular footing of radius \( B \), the load per unit area is equal to

\[ q = \frac{P}{\pi B^2} \quad (136) \]

the load \( q \) contributes a vertical stress \( d\sigma_z \) at point \( M \), by using equation (108)

\[ d\sigma_z = -\frac{3q}{2\pi R_1} \, dA \quad (137) \]

thus,

\[ \sigma_z = \frac{3q}{2\pi} \int_{A}^{R_1} \frac{3}{R_1} \, dA \quad (138) \]

where \( dA \) is given by equation (135).

\[ dA = rd\theta dr \quad (139) \]

From Figure 20,

\[ r = z \tan \alpha \quad (140) \]

therefore

\[ dr = \frac{z}{\cos^2 \alpha} \quad (141) \]
Substituting equations (139), (141) and (143) for equation (138), yields

\[
\sigma_z = \frac{3q}{2\pi} \int_0^{2\pi} \int_0^{\pi/2} \frac{z^5 \sin \alpha}{\cos^3 \alpha} \frac{1}{R_1^5} \, d\alpha \, d\beta
\]

(142)

From Figure 20, the following vectors can be obtained

\[ R_1 = |\overrightarrow{MN}| \]

\[ \overrightarrow{ON} = (r \cos \beta, r \sin \beta, 0) \]

\[ \overrightarrow{OM} = (x, 0, z) \]

then

\[ \overrightarrow{MN} = (r \cos \beta - x, r \sin \beta, z) \]

thus

\[ |\overrightarrow{MN}| = R_1 = \sqrt{(r^2 + x^2 - 2xr \cos \beta + z^2)^{1/2}} \]

but \( r = zt \cos \alpha \), equation (140), then

\[ R_1 = \frac{1}{\cos \alpha} \left( z^2 + x^2 \cos^2 \alpha - 2zx \sin \alpha \cos \alpha \cos \beta \right)^{1/2} \]

(143)

Substituting equation (143) in equation (142), yields

\[
\sigma_z = \frac{3qz^5}{2\pi} \int_0^{2\pi} \int_0^{\pi/2} \cos^2 \alpha \sin \alpha \, d\alpha \, d\beta \frac{\cos^2 \alpha \sin \alpha \, d\alpha}{(z^2 + x^2 \cos^2 \alpha - 2zx \sin \alpha \cos \alpha \cos \beta)^{5/2}}
\]

(144)

In the case where the point \( M \) is on the \( z \) axis \( x = 0 \), equation (144) yields the following

\[
\sigma_z = \frac{3qz^5}{2\pi} \int_0^{\pi/2} 2\pi \frac{\cos^2 \alpha \sin \alpha \, d\alpha}{z^5} = q(1 - \cos^3 \alpha)
\]

(145)

the horizontal component \( \sigma_x \) of the stresses is given by equation (107) as
\[
\sigma_x = \frac{3q}{\pi} \left( \frac{x^2 z}{R_1^5} + \frac{1-2\nu}{3} \frac{1}{R_1(R_1+z)} - \frac{(2R_1+z)x^2}{R_1^3(R_1+z)^2} - \frac{z}{R_1} \right)
\]

(107)

over the unit area \(dA\)

\[d\sigma_x = \sigma_x dA\]

integrating as before the vertical stress component is given by

\[
\sigma_x = \frac{3q}{\pi} \int_0^{2\pi} \int_0^{\infty} x^2 z \left( \frac{1}{R_1^5} + \frac{1-2\nu}{3} \frac{1}{R_1(R_1+z)} - \frac{(2R_1+z)x^2}{R_1^3(R_1+z)^2} - \frac{z}{R_1} \right) d\alpha d\beta
\]

(146)

Also, by using equation (109), the shear stress \(\tau_{xz}\) is equal to

\[
\tau_{xz} = \frac{3q}{\pi} \int_0^{2\pi} \int_0^{\infty} xz^2 \frac{1}{R_1^5} d\alpha d\beta
\]

(147)

because of symmetry \(\sigma_x = \sigma_y\) and \(\tau_{yz} = \tau_{xz}\); and the value of \(R_1\) is given by the equation (143).

3.4 STRIP FOOTING

The strip footing shown in Figure 21 is under a vertical line load \(p\), the load \(p\) is transmitted to the soil along the width \(2B\) of the footing. The unit applied load \(q\) at the surface is given by

\[q = \frac{p}{2B}\]

(148)

Referring to equation (56), the vertical component stress at point \(M\) at depth \(z\) is equal to

\[\sigma_z = \frac{2q z^3}{\pi R_1^4}\]

(149)
Figure 21. Figure showing the vectors and stresses analysis for a flat strip footing.
An incremental part of the load of width dS and intensity q acts at some distance S, from the center of the load. The vertical stress increment is given by

\[ d\sigma_z = \frac{2q}{\pi} \frac{z^3}{R_1^4} ds \]  \hspace{1cm} (150)

Using the polar coordinates and calculating \( d\sigma_z \) as a function of \( d\alpha \), from Figure 21, the following equation can be deduced

\[ \tan \alpha = \frac{s-x}{z} \quad \text{OR} \quad (s-x) = z \tan \alpha \]  \hspace{1cm} (151)

\[ \cos \alpha = \frac{z}{R_1} \quad \text{OR} \quad R_1 = \frac{z}{\cos \alpha} \]  \hspace{1cm} (152)

\[ \alpha_1 = \tan^{-1} \left( \frac{-x-B}{z} \right) \]  \hspace{1cm} (153)

\[ \alpha_2 = \tan^{-1} \left( \frac{-x+B}{z} \right) \]  \hspace{1cm} (154)

where \( \alpha_1 \) and \( \alpha_2 \) are the lower and upper limits of the angle \( \alpha \).

Differentiation of equation (151), yields

\[ ds = \frac{z}{\cos^2 \alpha} \ d\alpha \]  \hspace{1cm} (155)

The substitution of equations (152) and (155) for equation (150), yields

\[ d\sigma_z = \frac{2q}{\pi} \cos^2 \alpha d\alpha \]  \hspace{1cm} (156)

Integrating equation (156) between \( \alpha_1 \) and \( \alpha_2 \), the vertical stress is obtained by the superposition of all the contributions of the loads q.

Thus

\[ \sigma_z = \int_{\alpha_1}^{\alpha_2} \frac{2q}{\pi} \cos^2 \alpha d\alpha \]  \hspace{1cm} (157)
using any handbook of integration where
\[ \int \cos^2 \alpha \, d\alpha = \frac{1}{2} + \frac{\sin 2\alpha}{4} \]

(158)

Equation (157), yields
\[ \sigma_z = \frac{2q}{\pi} \left[ \frac{\alpha_1 - \alpha_2}{z} + \frac{1}{4} \left( \sin 2\alpha_2 - \sin 2\alpha_1 \right) \right] \]

(159)
or
\[ q = \frac{p}{2\beta} \quad \text{(equation 148)} \]

and
\[ \sin A - \sin \beta = 2 \sin \frac{A-B}{2} \cos \frac{(A+B)}{2} \]

(160)

substituting equations (148) and (160) for equation (159)
\[ \sigma_z = \frac{p}{2\pi K} \left[ (\alpha_2 - \alpha_1) + \sin \frac{(\alpha_2 - \alpha_1)}{2} \cos \frac{2\alpha_2 - \alpha_1}{2} \right] \]

(151)

where \( \sigma_z \) is the vertical stress at point M.

In a similar manner referring to equation (37), and replacing \( da \) by \( dS \), and \( x \) by \( s - x \), the increment of the horizontal stress is given by
\[ d\sigma_x = \frac{2q}{\pi} \frac{z(s-x)^2}{R^4} \, ds \]

(161)

substituting equations (151), (152) and (155) in equation (160), then
\[ d\sigma_x = \frac{2qz}{\pi} \left( \frac{z^2 q^2 \alpha}{4} \frac{z}{\cos^4 \alpha} \, da \right) \]

(162)

\[ d\sigma_x = \frac{2q}{\pi} \left( \sin^2 \alpha \, da \right) \]
Integrating from \( \alpha_1 \) to \( \alpha_2 \)

\[
\sigma_x = \frac{2g}{\pi} \int_{\alpha_1}^{\alpha_2} \sin^2 \alpha \, d\alpha
\]  

(163)

where

\[
\int \sin^2 \alpha = \frac{\alpha}{2} - \frac{\sin 2\alpha}{4}
\]  

(164)

thus,

\[
\sigma_x = \frac{2g}{\pi} \left( \frac{\alpha_2 - \alpha_1}{2} - \frac{\sin 2\alpha_2 - \sin 2\alpha_1}{4} \right)
\]  

(165)

Substituting equations (148) and (160) in equation (164), yields

\[
\sigma_x = \frac{p}{2mB} \left[ (\alpha_2 - \alpha_1) - \sin \frac{(\alpha_2 - \alpha_1)}{2} \cos \frac{(\alpha_2 + \alpha_1)}{2} \right]
\]  

(166)

Therefore, the same analysis to calculate the shear stress, equation (58) can be satisfied.

\[
\tau_{xz} = \frac{2g}{\pi} \frac{xz^2}{R^4}
\]  

(58)

\[
d\tau_{xz} = \frac{2g}{\pi} \frac{z^2(s-x)}{R^4} \, ds
\]  

(167)

\[
= \left( \frac{2g}{\pi} \frac{z^2}{R^4} \right) \left( \frac{\ln \tan \frac{\alpha}{2} - \frac{z}{\cos^2 \alpha}}{\cos \alpha} \right) d\alpha
\]

\[
= \frac{2g}{\pi} \sin \alpha \cos \alpha \, d\alpha
\]

thus

\[
\tau_{xz} = \frac{2g}{\pi} \int_{\alpha_1}^{\alpha_2} \sin \alpha \cos \alpha \, d\alpha
\]  

(168)
\[ \tau_{xz} = \frac{q}{\pi} \left( \sin^2 \alpha \right) \left| \alpha \right| \]  
\[ \tau_{xz} = \frac{P}{2\pi B} \left( \sin^2 \alpha - \sin^2 \alpha_1 \right) \]  

the horizontal component stress \( \sigma_y \) is given by equation (46), as

\[ \sigma_y = \nu(\sigma_x + \sigma_z) = \nu \frac{q}{\pi B} (\alpha_2 - \alpha_1). \]  

(170)

### 3.5 CYLINDRICAL STRIP FOOTING.

The strip footing in Figure 22, has a cylindrical shape. The force \( P \) per unit length \( P \) is applied in the \( z \) direction.

Assuming that, the intensity of contact pressure between the soil and the foundation is \( q_0 \), the foundation settles uniformly because of symmetric loading and shape, after paragraph 2.4 of Chapter II. The vertical load \( q \) by unit length and unit width \( ds \) is a constant denoted by \( q_0 \).

Dividing the circular foundation into smaller segments, each having an angle \( d\alpha \) (as shown in Figure 23). With the lower and upper limits at \( \alpha \) are \( -\alpha_0 \) and \( \alpha_0 \), respectively.

Assume: \( R \): is the radius of the circle

\( S \): is the horizontal coordinate of the point \( N \), where the vertical load \( q_0 \) is acting

\( 2B \): is width of the footing.
Figure 22. Shows the cylindrical strip footing.

Figure 23. A sector divided into equal portions of value $d\alpha$. 
Figure 23, shows the following
\[ s = R \sin \alpha \]  
\[ \alpha_0 = \sin^{-1} \left( \frac{B}{R} \right) \]
(171)
(172)

Differentiating equation (170), the following is obtained:
\[ ds = R \cos \alpha \, d\alpha \]
(173)

then
\[ q = q_0 \, ds = q_0 R \cos \alpha \, d\alpha \]
(174)

For equilibrium on cylindrical foundation, the total vertical line load acting on the soil \((q_0'/\text{unit area})\)· \(ds\) is equal to the initial load per unit length.

\[ P = \sum q \, ds = \int_{-\alpha_0}^{\alpha_1} q_0 R \cos \alpha \, d\alpha \]

\[ = 2q_0 R \sin \alpha_0. \]

where \( R \sin \alpha_0 = A \) (from equation (161)).

and

\[ qds = \frac{p}{2B} R \cos \alpha \, d\alpha. \]

(175)

The stresses due to \( q \) at point \( M \) in Figure 24, can be evaluated by using equations (110) to (112), developed by Melan's (1932).

For the vertical components \( \sigma_z \) using equation (111) \( \sigma_z = V \frac{q}{\pi} \) by replacing \( x \) by \((s-x) = w\), where

\[ V = \frac{1}{2(1-\nu)} \left[ \frac{(z-d)^3}{R_1^4} + \frac{(z+d)(z+d)^2 + \omega dz}{R_2^4} - \frac{8dz(d+z)w^2}{R_2^6} \right. \]

\[ + \left. \frac{1-\nu}{4(1-\nu)} \left( \frac{z-d}{R_1^2} + \frac{3z+d}{R_2^2} - \frac{4zw^2}{R_2^4} \right) \right] \]

(176)
the Figure 24 shows that

d: is the vertical distance where the load acts.

\[ |\overline{MN}| = R_1 \]

\[ |\overline{MT}| = R_2 \]  \hspace{1cm} (177)

\[ |\overline{NT}| = 2d \]

in the \((O_1, x, z)\) system, the vectors \(O_1N\) and \(O_1M\) are equal to

\[ O_1N = (R \sin \alpha, R \cos \alpha) \]

\[ O_1M = (x, r-z) \]

in \((O, x, z)\) system:

\[ \overline{ON} = (R \sin \alpha, R - R \cos \alpha) \]

\[ \overline{OM} = (x, z) = \text{constant} \]

\[ \overline{OT} = (x_N, -z_N) = (R \sin \alpha, R \cos \alpha - R) \]

\[ \overline{MN} = \overline{ON} - \overline{OM} = ((R \sin \alpha - x), (R - R \cos \alpha - z)) \]

\[ \overline{MT} = \overline{OT} - \overline{OM} = ((R \sin \alpha - x), (R \cos \alpha - R - z)) \]

then the values of \(R_1, R_2, d\) and \(\omega\) are equal to

\[ R_1 = |\overline{MN}| = ((R \sin \alpha - x)^2 + (R - R \cos \alpha - z)^2)^{1/2} \]  \hspace{1cm} (178)

\[ R_2 = |\overline{MT}| = ((R \sin \alpha - x)^2 + (R \cos \alpha - R - z)^2)^{1/2} \]  \hspace{1cm} (179)

\[ d = |\overline{N}N| = R - R \cos \alpha \]  \hspace{1cm} (180)

\[ \omega = R \sin -x \]  \hspace{1cm} (181)

As for a strip footing for an increment \(da\), the vertical stress increment is obtained by using equations (175) and (176) as.
Figure 24. Figure showing the vectors and stresses for a cylindrical strip footing.
\[ \sigma_z = \frac{PR}{2B \pi} \int_{-\alpha_0}^{\alpha_0} \cos \alpha \left[ \frac{1}{2(1-\nu)} \left( \frac{(z+d)^3}{R_1^4} + \frac{(z+d)((z+d)^2+2dz)}{R_2^4} \right) ight. \]

\[ - \frac{8dz(d+z)w^2}{R_2^6} \left] \right. + \frac{1-2\nu}{4(1-\nu)} \left( \frac{z-d}{R_1^2} + \frac{3z+d}{R_2^2} - \frac{4zw^2}{R_2^6} \right) \]

where \( R_1, R_2 \) and \( d \) are given by equations (178), (179) and (180).

Similarly for the horizontal components, using equation (110)

\[ \sigma_x = \frac{PR}{2B \pi} \int_{-\alpha_0}^{\alpha_0} \cos \alpha \left[ \frac{1}{2(1-\nu)} \left( \frac{(z-d)w^2}{R_1^4} + \frac{(z+d)(w^2+2d^2)-2dw^2}{R_2^4} \right) \right. \]

\[ + \frac{8dz(d+z)w^2}{R_2^6} \left] + \frac{1-2\nu}{4(1-\nu)} \left( \frac{d-z}{R_1^2} + \frac{z+3d}{R_2^2} + \frac{4zw^2}{R_2^4} \right) \right) \]

and the shear stress \( \tau_{xz} \) using equation (112) is equal to

\[ \tau_{xz} = \frac{PR}{2B \pi} \int_{-\alpha_0}^{\alpha_0} \cos \alpha \left[ \frac{1}{2(1-\nu)} \left( \frac{(z-d)^2}{R_1^4} + \frac{z^2-2dz-d^2}{R_2^4} + \frac{8dz(d+z)^2}{R_2^6} \right) \right. \]

\[ + \frac{1-2\nu}{4(1-\nu)} \left( \frac{1}{R_1^2} - \frac{1}{R_2^2} + \frac{4zd(d+z)}{R_2^4} \right) \right) \]

the value of each integral is obtained by using numerical analysis (the subroutine DCADRE in the library of Computer Science at Concordia University was used).
3.6 TRIANGULAR STRIP FOOTING.

By considering the shape of the footing as triangular (as shown in Figure 25), it is taken that the width of the footing is 2B and the peak angle is $\theta$. In addition, the triangular footing is divided into equal segments $ds$.

Assuming $q_0$ is the vertical load by unit area (taken at point load) the vertical line load $q$ is a constant

$$q = q_0 \, ds$$  \hspace{1cm} (185)

As it is stated in equilibrium conditions, the sum of the vertical loads are equal to zero, therefore

$$\Sigma q - P = 0$$  \hspace{1cm} (186)

where

$$q_0 = \frac{P}{2B} \text{ / unit area}$$  \hspace{1cm} (187)

$$q = \frac{P}{2B} \, ds/\text{unit length}$$  \hspace{1cm} (188)

In order to analyse the stress components at point $M$ below the ground level, the analysis of the footing described above will be similar to the analysis of the strip footing.

From Figure 26, let

$$R_1 = |MN|; \quad R_2 = |TM| \quad \text{and} \quad |TN| = 2d$$  \hspace{1cm} (189)

where

$$d = \frac{s}{\tan \beta}$$  \hspace{1cm} (190)

d is always positive, then if $s$ is positive

$$d = \frac{s}{\tan \beta}$$  \hspace{1cm} (191)
Figure 25. Shows the triangular strip footing.

Figure 26. Figure showing the vectors and stresses on a cylindrical strip footing.
and if $s$ is negative

$$d = \frac{-s}{\tan \beta}$$  \hspace{1cm} (192)

The following vectors can be written as

$$\overline{OM} = (x, z)$$  \hspace{1cm} (193)

$$\overline{ON} = (s, d)$$  \hspace{1cm} (194)

$$\overline{OT} = (s, -d)$$  \hspace{1cm} (195)

$$\overline{NM} = \overline{ON} - \overline{OM} = (s-x, z-d)$$  \hspace{1cm} (196)

$$\overline{TN} = \overline{ON} - \overline{OT} = (s-x, z+d)$$  \hspace{1cm} (197)

Assume that

$$W = s - x$$  \hspace{1cm} (198)

then the modulus of the vectors $\overline{NM}$ and $\overline{TN}$ are equal to

$$R_1 = |\overline{NM}| = \sqrt{(s-x)^2 + (z-d)^2}^{1/2}$$  \hspace{1cm} (199)

$$R_2 = |\overline{TN}| = \sqrt{(x-s)^2 + (z+d)^2}^{1/2}$$  \hspace{1cm} (200)

assuming

$$C_2 = \frac{p}{2\pi B}$$  \hspace{1cm} (201)

an increment part of the load over width $ds$, the vertical stress increase

$\frac{dz_2}{dz}$, integrating $\frac{dz_2}{dz}$ from $-B$ to $+B$, yields

$$c_2 = \int_{-B}^{B} C_2 \left( \frac{1}{2(1-\nu)} \frac{(z-d)^3}{R_1^4} + \frac{(z+d)(z+d)^2}{R_2^4} + \frac{2dz}{R_2} \right)$$

$$- \frac{8dz(d+z)w^2}{R_2^6} + \frac{1-2\nu}{4(1-\nu)} \left( \frac{z-d}{R_1^2} + \frac{3z+d}{R_2^2} - \frac{4zw^2}{R_2^4} \right) \, ds$$  \hspace{1cm} (202)
Similarly for the horizontal component of the stress, \( \sigma_x \) is equal to

\[
\sigma_x = \int C_2 \left[ \frac{1}{1-2\nu} \left( \frac{(z-d)^2}{R_1^4} + \frac{(z+d)(w^2+2d^2)-2dz^2}{R_2^4} \right) \right. \\
- \frac{8d(z+d+z)}{R_2^6} + \frac{1-2\nu}{4(1-\nu)} \left. \left( \frac{d-z}{R_1^2} + \frac{d+z}{R_2^2} + \frac{4zw^2}{R_4^2} \right) \right] \, ds
\]

(203)

And the shear stress \( \tau_{xz} \) is given by

\[
\tau_{xz} = \int_{-B}^{B} C_2 \left[ \frac{1}{2(1-\nu)} \left( \frac{(z-d)^2}{R_1^4} + \frac{z^2-2dz-d^2}{R_2^4} + \frac{8dz(d+z)^2}{R_2^6} \right) \right. \\
+ \frac{1-2\nu}{4(1-\nu)} \left. \left( \frac{1}{R_2^2} - \frac{1}{R_2^2} + \frac{4z(d+z)}{R_2^4} \right) \right] \, da
\]

(204)

where \( R_1, R_2, d \) and \( C_2 \) are given by the equations (199), (200), (190) and (201). The upper and lower limits \( AL \) and \( BL \) are given by the following equation

\[
AL = -B \quad \text{and} \quad BL = B.
\]

(205)

3.7 SPHERICAL FOOTING.

The footing Figure 27, is a portion of a sphere, where the center \( O_1 \) is located at depth \( R \) from the ground level. The load \( P \) is acting on the soil as sum of unit load \( q \) acting on a unit surface \( dA \) (see Figure 28).

The coordinates system \( O_1(x, y, z) \) will be used to determine the geometric characteristics for the surface of the sphere, which is defined
Figure 27. Figure showing a spherical footing.

Figure 28. Vectors analysis for the unit infinitesimal area dA.
by a vector \( \overrightarrow{O_1N} \) as

\[
\overrightarrow{O_1N} = (x, y, z_1)
\]

where

\[
\begin{align*}
x &= R \sin \alpha \cos \beta \\
y &= R \sin \alpha \sin \beta \\
z_1 &= R \cos \alpha
\end{align*}
\]  

(205)

the angles \( \alpha \) and \( \beta \) are shown in Figure 28, as the parameters of the coordinates \( x, y, z_1 \).

The first derivative of the vector \( \overrightarrow{O_1N} \) is obtained by

\[
\begin{align*}
\frac{d}{dt} \overrightarrow{O_1N}_\alpha &= (-R \cos \alpha \cos \beta, R \cos \alpha \sin \beta, -R \sin \alpha) \\
\frac{d}{dt} \overrightarrow{O_1N}_\beta &= (-R \sin \alpha \cos \beta, R \sin \alpha \sin \beta, 0)
\end{align*}
\]

(206)  

(207)

The unit area \( dA \) can be obtained by using the equation (128)

\[
dA = |\overrightarrow{ON}_\alpha \times \overrightarrow{ON}_\beta| = |\overrightarrow{ON}_\alpha| \ |\overrightarrow{ON}_\beta| \ \sin \omega \ d\alpha \ d\beta
\]

(128)

where \( \omega \) is the angle between the two vectors \( \overrightarrow{O_1N}_\alpha \) and \( \overrightarrow{O_1N}_\beta \). However, the scalar product of these two vectors is zero, therefore

\[
\omega = \frac{\pi}{2} \quad \text{and} \quad \sin \omega = 1.
\]

(208)

the modulus \( |\overrightarrow{O_1N}_\alpha| \) and \( |\overrightarrow{O_1N}_\beta| \) are given by

\[
\begin{align*}
|\overrightarrow{O_1N}_\alpha| &= (R^2 \cos^2 \alpha \cos^2 \beta + R^2 \cos^2 \alpha \sin^2 \beta + R^2 \sin^2 \alpha)^{1/2} \\
&= (R^2 \cos^2 \alpha (\cos^2 \beta + \sin^2 \beta) + R^2 \sin^2 \alpha)^{1/2} = R \\
|\overrightarrow{O_1N}_\beta| &= (R^2 \sin^2 \alpha \sin^2 \beta + R^2 \sin^2 \alpha \cos^2 \beta)^{1/2} \\
&= R \sin \alpha.
\end{align*}
\]

(209)  

(210)

Substituting equations (208), (209) and (210) for equation (128), the
following value is obtained
\[ dA = R^2 \sin \alpha \: d\alpha \: d\beta. \] (211)

The projection of the area \( dA \) on \( x \) \( y \)-plane is given by
\[ dA = dA \cos \alpha = R^2 \sin \alpha \cos \alpha \: d\alpha \: d\beta. \] (212)

However, \( \alpha \) and \( \beta \) are two independent angles, and \( \alpha \) varies from zero to \( \alpha_0 \) and \( \beta \) varies from zero to \( 2\pi \), where
\[ \alpha_0 = \sin^{-1}\left(\frac{B}{R}\right) \] (213)

The center of the sphere shown in Figure 29 located at the point \( O \) it is at a distance of \( OO_1 \) from the original center \( O \) of the system of coordinates \( O(x, y, z) \), with a positive sense of direction of the \( z \)-axis pointing downwards.

Let \( N \) be the point of contact between the soil and the sphere at which the point load \( q \) is acting, \( q \) is taken as a unit load. The projection of point \( N \) on the \( x \), \( y \)-plane is the point \( H \), while \( T \) is the point symmetric to \( N \), with respect to the \( x \), \( y \)-plane.

Therefore,
\[ |\overrightarrow{NH}| = |\overrightarrow{HT}| = d \] (214)

Let \( M \) be any point in the soil with \((x, y, z)\) coordinates, for which the stresses can be calculated. The modulus of the vectors \( \overrightarrow{NM} \) and \( \overrightarrow{TM} \) are given by
\[ |\overrightarrow{NM}| = R_1 \] \[ |\overrightarrow{TM}| = R_2. \] (215)

However, the following vectors can be obtained by
\[ \overrightarrow{OM} = (x_M, y_M, z_M) \]
Figure 29. Figure showing the vectors and stresses analysis for a spherical footing.
\[ \overrightarrow{ON} = (x_N, y_N, z_N) = (R \sin \alpha \cos \beta, R \sin \alpha \cos \beta, R - R \sin \alpha) \]
\[ \overrightarrow{ON} = (x_N, y_N, -z_N) \]
\[ \overrightarrow{MN} = \overrightarrow{ON} - \overrightarrow{OM} \]
\[ = ((x_N - x_M), (y_N - y_M), (z_N - z_M)) \]  
(216)

and
\[ \overrightarrow{TN} = \overrightarrow{OT} - \overrightarrow{OM} \]
\[ = ((x_T - x_M), (y_T - y_M), (z_T - z_M)) \]  
(217)

After replacing the coordinates by their values the distance \( R_1 \), \( R_2 \) and \( d \) is found as follows
\[ R_1 = |\overrightarrow{MN}| = ((R \sin \alpha \cos \beta - x)^2 + (R \sin \alpha \cos \beta - y)^2 \]
\[ + (R - R \cos \alpha - z)^2)^{1/2} \]  
(218)
\[ R_2 = |\overrightarrow{MT}| = ((R \sin \alpha \cos \beta - x)^2 + (R \sin \alpha \cos \beta - y)^2 \]
\[ + (R - R \cos \alpha + z)^2)^{1/2} \]  
(219)
\[ d = R - R \cos \alpha. \]  
(220)

The vertical stress at point \( M \) can be obtained by superposition of all the partial vertical stresses acting on differential unit area \( dA \) on the footing. Let \( V \) equal to \( \sigma_z \) as given in equation (118) developed by Mindlin (1936)
\[ d\sigma_z = q \ V \ dA \]  
(221)

However, \( dA \) is given by equation (211) as
\[ dA = R^2 \sin \alpha \cos \alpha \ d\alpha \ d\beta \]
Substituting equation (211) in equation (221) and integrating along the spherical surface limited by the footing. The vertical stress at a point \( M \) is given as follows

\[
\sigma_z = \frac{qR^2}{8\pi(1-\mu)} \int_0^{2\pi} \int_0^{\alpha_0} \sin \alpha \cos \alpha \left[ \frac{(1-2\nu)(z-d) + (1-2\nu)(z-d)}{R_3} \right] \, d\alpha \, dx
\]

\[
- \frac{3(z-d)^3}{R_1^5} \left[ \frac{3(3-4\nu)z(z+d)^2}{R_2^3} - \frac{3d(z+d)(5z-d)}{R_2^3} - \frac{3dz(z+d)^3}{R_2^7} \right] \, dx
\]

Similarly for the horizontal component \( \sigma_x \) can be obtained by using the same procedure as for the vertical stress component, by integrating the value of \( \sigma_x \) given by equation (117)

\[
\sigma_x = \frac{qR^2}{8\pi(1-\nu)} \int_0^{2\pi} \int_0^{\alpha_0} \sin \alpha \cos \alpha \left[ \frac{(1-2\nu)(z-d) - 3\nu^2(z-d)}{R_1^3} \right] \, d\alpha \, dx
\]

\[
+ \frac{(1-2\nu)(3(z-d) + 4\nu(z+d))}{R_2^3}
\]

\[
- \frac{(3-4\nu)x^2(z-d) - 6d(z+d)(1-2\nu)z - 2\nu x}{R_2^5}
\]

\[
- \frac{30d x^2(z+d)}{R_2^7} + \frac{4(1-\nu)(1-2\nu)}{R_2(R_2 + z + d)} \times \left( 1 - \frac{x^2}{R_2(R_2 + z + d)} - \frac{x^2}{R_2} \right) \, d\alpha
\]

also the shear stress can be obtained by using the same procedure as before, by integrating the value of \( \tau_{xz} \) given by equation (119)
\[
\tau_{xz} = \frac{\sigma R^2}{8\pi(1-\mu)} \int_0^{2\pi} \int_0^z \sin \alpha \cos \alpha \left[ -\frac{(1-2\nu)}{R_1^3} + \frac{1-2\nu}{R_2^3} - \frac{3(z-d)^3}{R_1^3} \right] \, dx 
\]

(224)

\[
\frac{3(3-4\nu)z(z+d) - 3d(3z+d) - 30dz(z+d)^3}{R_2^5} \int_0^{2\pi} \int_0^z \sin \alpha \cos \alpha \left[ -\frac{1-2\nu}{R_1^3} + \frac{1-2\nu}{R_2^3} - \frac{3(z-d)^3}{R_1^3} \right] \, dx 
\]

the stress components \(\sigma_y\) and \(\tau_{yz}\) are equal to the stress components \(\sigma_x\) and \(\tau_{xz}\) respectively, because the load and the footing are symmetric about the \(z\)-axis.

### 3.8 The S-Sin Strip Model

The model strip foundation has a width of 2\(B\) (see Figure 30), and the curvature is a function of \(\sin S\) as

\[
Z = \sin^2 (\pi S). \tag{225}
\]

The vector analysis for this model (see Figure 31), is similar to the analysis mode for the triangular models. Again, a rigid foundation is considered and the load intensity is linearly proportional to the unit length, \(dS\). Referring to the equations (202), (203) and (204), the modulus of the vectors \(\overline{MN}\) and \(\overline{MT}\) is given by

\[
|\overline{MN}| = R_1 = \sqrt{w^2 + (z-d)^2} \tag{226}
\]

\[
|\overline{MT}| = R_2 = \sqrt{w^2 + (z+d)^2} \tag{227}
\]

where

\[
d = \sin^2 (\pi S) \tag{228}
\]

\[
w = S - X \tag{229}
\]

and

\(S\) varies between -\(B\) to \(B\).
Figure 30. The shape of the model $S\sin$.

Figure 31. Figure showing the vectors and stresses analysis for the shape $S\sin$. 
3.9 COMPUTER PROGRAM

The following program is coded to analyze stresses for the models proposed in this paper.

Five main programs are used, each consists of a main program and 9 subroutines. All programs are similar, except data input and the subroutine which computes the geometric characteristics of each model.

As an example, a typical program is shown below as a flat strip, and cylindrical modes.

The rectangular coordinates are used in case of flat, triangular and S-sin models.

The polar coordinates system is used in case of cylindrical models.

The polar coordinates system is used in case of cylindrical strip and circular plate modes.

The spherical coordinates system is used in case of spherical models.

All the details of the main program and the subroutines are explained in the program itself as comments.

CHAPTER IV

RESULTS AND ANALYSIS

4.1 GENERAL

The computer program developed in the present study (Chapter III) to determine stress distribution. Below different foundation levels have been used extensively to generate data, for the purpose of comparison between different foundation models and to draw a conclusion.

4.2 PROGRAM DATA

The program is divided into subroutines to evaluate the stress distribution, the load applied is: a unit line load per unit length, or a unit load per unit area. The width of the foundation is always equal to 2B.

For the flat footing strip or circular, only Poisson's ratio \( \nu \) is needed to execute this part of the program.

For the new proposed models only one variable is required, which depends on the shape of the foundation. For example, for the cylindrical foundation (see Figure 32-b). The radius of the circle \( R \) is the variable and for the triangular foundation, the angle peak has a value of 2\( \theta \), the same data is used for the spherical and the circular foundation, where the variable is the radius \( R \).
a. **Flat strip foundation.**

b. **C1:** cylindrical model with radius $R = B$.
   **C2:** cylindrical model with radius $R = 2B$. 

c. \( T_{30} \): Triangular model with angle \( \beta = 30^\circ \).
\( T_{45} \): Triangular model with angle \( \beta = 45^\circ \).

\[ \text{Figure 32. Shows different types of footing.} \]
Example of data:

For the cylindrical model

-5 (μ)
1 R
3 R
2000 R

For the triangular model

-5 (μ)
30 (β)
45 (β)
90 (β)

NOTE: Where R = 2000 or β = 90°, the two above models will work as a flat strip footing.

For the strip footing, where the shape is a function of sin πS called S sin

Z = sin²(πS)

the Poisson's ratio μ is the only data required.

4.3 PROGRAM OUTPUT

The mesh of location of the points, where the stresses are analysed (shown in Figure 33). In the horizontal direction, the first point is at S = -2B and the last point is at S = 2B, and the distance between two successive is .5B. However, in the Z direction the analysis is done at eight levels, the first level is Z = .5B, and the last one is Z = 4B.
Figure 33. This mesh indicates the location of the points, where the stresses are calculated.

4.4 **TYPICAL GRAPHS**

Tests summarized in section 4.3 are presented, some typical in graphical forms.

Figure 32, shows the model configurations used.

Figure 33, shows the location of the points, where the stresses are calculated.

Figures 34, 35 and 36, show the vertical stresses respectively at levels equal to \( \cdot 5B \), \( B \) and \( 1 \cdot 5B \) respectively, for the flat and cylindrical strip models.

Figures 37, 38 and 39, show the vertical stresses at level \( z \) equal to \( \cdot 5B \), \( B \) and \( 1 \cdot 5B \) respectively, for the flat and triangular models.

Figures 40, 41 and 42, show the vertical stresses at level \( z \) equal to \( \cdot 5B \), \( B \) and \( 1 \cdot 5B \) respectively, for a S-sin model.

Figures 43, 44 and 45, show the vertical stresses at the middle, at \( x \) equal to \( \cdot 5B \) and at \( x \) equal to \( B \) respectively, for the flat and S-sin models.

Figures 46, 47 and 48, show the horizontal stresses at level \( z \) equal to \( \cdot 5B \), \( B \) and \( 1 \cdot 5B \) respectively, for the flat and S-sin models.

Figures 50, 51 and 52, show the shear stresses at level \( z \) equal to \( \cdot 5B \), \( B \) and \( 1 \cdot 5B \) respectively, for the flat and S-sin models.
Figure 34. Vertical stresses at depth $Z = 0.5B$ for flat and cylindrical models.
Figure 35. Vertical stresses at depth $z = B$
for flat and cylindrical models.
Figure 36. Vertical stresses at $Z = 1.5B$ for cylindrical and flat models.
Figure 17. Vertical stresses at depth $Z = 0.5B$ for flat and triangular models.
Figure 38. Vertical stresses at depth \( Z = B \) for flat and triangular models.
Figure 39. Vertical stresses at depth $Z = 1.5B$ for flat and triangular models.
Figure 40. Vertical stresses at depth $z = 0.5B$

for flat and $S$-sin models.
Figure 41. Vertical stresses at depth $Z = B$
for flat and S-sin models.
Figure 42. Vertical stresses at depth $z = 1.5B$ for flat and $S$-sin models.
Figure 43. Vertical stresses at $X = 0$
for flat and $S$-sin models.
Figure 44. Vertical stresses at width \( x = -5B \)
for flat and \( S\)-sin models.
Figure 45. Vertical stresses at width $x = 3$
for flat and $S$-sin models.
Figure 46. Horizontal stresses at $Z = -5B$
for flat and $S$-sin models.
Figure 47. Horizontal stresses at $Z = B$ for flat and S-sin models.
Figure 48. Horizontal stresses at $Z = 1.5B$ for flat and $S$-sin models.
Figure 49. Shear stress at depth $z = -0.5B$
for flat and S-sin models.
Figure 50. Shear stresses at depth $Z = B$
for flat and S-sin models.
Figure 51. Shear stresses at $Z = 1.5B$ for flat and $S$-sin models.
CHAPTER V

CONCLUSION AND RECOMMENDATION

The present study is an attempt to introduce new foundation models, to increase bearing capacity and to reduce settlement, resulting in economical foundation design. These models had shapes of arched and sloped ones.

Stress analysis was conducted on the soil beneath these proposed models and the conventional flat footings. The results were presented in the form of a ratio of the deduced stress at a given point, due to the proposed model and the conventional flat foundations. The results were presented in Tables and Figures, where the following conclusion can be drawn:

1. The proposed models have provided better distribution and lesser in amount of the vertical compression stress up to a depth of about 2.5 of the foundation width. It is believed that the compression of this depth produces up 90% of the foundation settlements. Thus, it can be stated that the proposed foundation models, will produce less settlement than the conventional footing which has the same width and under the same loads.

2. The proposed models produce less shear and horizontal stresses than the conventional flat one. Thus, the proposed foundation models will have higher bearing
capacity than the conventional footings.

It is submitted, however, that the work presented here is the first attempt in searching for foundation shapes, to increase its bearing capacity and to reduce its settlements. Thus, efforts should be made in the future:

1 - Utilize the computer program coded for the propose of this study, to optimize models' shapes in order to achieve better improvements. Other shapes may be considered, such as stepped ones.

2 - Study of feasibility on the construction of these new foundation models, should be conducted and construction techniques should be developed to facilitate and economize the field construction.
