## Abstract

## Deformations of Galois representations

## Clara Lacroce

In this thesis we study a paper by Barry Mazur ([11]) about deforming Galois representations. In particular we will prove that, if $\bar{\rho}: \Pi \rightarrow \mathrm{GL}_{N}(k)$ is an absolutely irreducible residual representation, a universal deformation ring $R=R(\Pi, k, \bar{\rho})$ and a universal deformation $\boldsymbol{\rho}$ of $\bar{\rho}$ to $R$ exist. This result is part of the proof of the modularity conjecture.

The modularity conjecture is of great importance since it states a connection between modular forms and elliptic curves over $\mathbb{Q}$, providing a great tool to study the arithmetic properties of those elliptic curves. Andrew Wiles studied the conjecture as a part of the more general problem of relating two-dimensional Galois representations and modular forms and used [11] to complete his construction.

To better understand the proof of Mazur, we will analyze in detail the paper of Michael Schlessinger ([13]). This article, which is focused on functors over Artin rings, provides a criterion for a functor to be pro-representable. Moreover, it gives the definition of a "hull", which is a weaker property than pro-representability.

To Silvano Gregori, who guided me to this world.

## Acknowledgments

I am sincerely grateful to Professor Adrian Iovita, for the patience in dealing with me and for his constant help during the developing of this Thesis. A big thanks goes to him also for all the advice he gave me during the year in Canada and for the devotion and inspiring passion he shows in his work.

My warmest acknowledgment goes to Maria Rosaria Pati, friend and irreplaceable workmates. I am thankful for all her precious and infinite help: having the chance of working on Schlessinger's paper together it has been stimulating and challenging.

My deepest gratitude goes to Lucas Berry, for his perseverance and his constant and unconditional support, and Mattia Tinotti, for his incredible intuition and for the advice he always give me in $\mathrm{AT}_{\mathrm{E}} \mathrm{X}$.

I would like to thank the graduate students of Concordia Math Department, my second family, in particular the number theorists Fabian Franken, for the corrections, Patrick Meisner and Jake Chinis for the suggestions.

I finally want to acknowledge my family, who always respect, support and encourage me in every choice of my life.

## Chapter 1

## Background Material

### 1.1 Group Theory

### 1.1.1 Inverse limits

We are now going to define the concept of inverse limit in the more general setting of category theory ([6]).

Definition 1.1. A directed set is a partially ordered set $A$ in which for any $\alpha, \beta \in A$ there exists $\gamma \in A$ such that $\alpha \leq \gamma$ and $\beta \leq \gamma$.

Definition 1.2. Let $C$ be a category, an inverse system in $C$ consists of a directed set $A$, a collection of objects $\left\{X_{\alpha}\right\}_{\alpha \in A}$ of $C$ and a morphisms $\pi_{\beta \alpha}: X_{\beta} \rightarrow X_{\alpha}$ for any $\alpha \leq \beta$ such that:
(i) $\pi_{\alpha \alpha}=i d_{X_{\alpha}}$ for all $\alpha \in A$
(ii) $\pi_{\beta \alpha} \cdot \pi_{\gamma \beta}=\pi_{\gamma \alpha}$ whenever $\alpha \leq \beta \leq \gamma$

Definition 1.3. Let $C$ be a category and $\left(A,\left\{X_{\alpha}\right\},\left\{\pi_{\beta \alpha}\right\}\right)$ an inverse system in $C$. An object $X \in O b(C)$ is called an inverse limit of this system if there exist morphisms $\pi_{\alpha}: X \rightarrow X_{\alpha}$ for $\alpha \in A$ with the following property:
(i) For any $\alpha \leq \beta$ the following diagram commutes:

(ii) Given any $Y \in O b(C)$ and morphisms $\phi_{\alpha}: Y \rightarrow X_{\alpha}$ such that the diagram:

commutes for $\alpha \leq \beta$, there exists unique morphism $\phi: Y \rightarrow X$ such that the following diagram commutes for all $\alpha \in A$ :

If an inverse limit exists, it is unique up to $C$-isomorphism and is denoted by $\underset{\leftrightarrows}{\lim } X_{\alpha}$. In particular, inverse limits always exist in the categories of sets, groups and rings and admit the following description:

$$
\lim _{\leftrightarrows} X_{\alpha}=\left\{\left(x_{\alpha}\right) \in \Pi X_{\alpha} \text { s.t. } \pi_{\beta \alpha}\left(x_{\beta}\right)=x_{\alpha} \text { for all } \alpha \leq \beta\right\}
$$

### 1.1.2 Profinite Groups

Definition 1.4. A profinite group is a topological group that is isomorphic to the inverse limit of an inverse system of discrete finite groups. It is an Hausdorff, compact and totally disconnected topological group.

Definition 1.5. The profinite completion of a group $G$ is the inverse limit of $G / N$, where $N \triangleleft G,|G: N|$ finite.

We notice that, if $F$ is a perfect field and $\bar{F}$ is its algebraic closure, $G_{F}=\operatorname{Gal}(\bar{F} / F)$ is a profinite group. More precisely, $G_{F}=\lim _{\leftarrow} \operatorname{Gal}(L / F)$ as $L$ runs over finite Galois extensions of $F$ contained in $\bar{F}$. In particular this works for $F=\mathbb{Q}$.

Let $p>0$ be a prime integer, $\Pi$ a profinite group. Following [12] we state the following definitions.

Definition 1.6. $\Pi$ is said to satisfy the finitness condition $\phi_{p}$ if for every open subgroup of finite index $\Pi_{0} \subset \Pi$ the following equivalent conditions hold:
(a) The pro-p-completion of $\Pi_{0}$ is topologically finitely generated (i.e. there is a finite number of generators whose closure generate the pro- $p$-completion of $\Pi_{0}$ );
(b) The abelianized pro- $p$-completion of $\Pi_{0}$, given its natural $\mathbb{Z}_{p}$-module structure, is of finite type over $\mathbb{Z}_{p}$;
(c) There are only a finite number of continuous homomorhisms from $\Pi_{0}$ to $\mathbb{F}_{p}$, i.e. $\operatorname{dim}_{\mathbb{F}_{p}}\left(\operatorname{Hom}_{\text {cont }}\left(\Pi_{0}, \mathbb{F}_{p}\right)\right)<\infty$

Examples of profinite groups $\Pi$ satisfying $\phi_{p}$ for all $p$, are given by groups arising as algebraic fundamental groups of smooth (geometrically connected) schemes of finite type over $\mathbb{Z}$.

In particular, for $K$ any number field and $S$ any finite set of primes of $K$, we may take $\Pi=G_{K, S}$ the Galois group of the maximal field extension of $K$ in an algebraic closure, which is unramified outside $S$ (in fact any open subgroup $\Pi_{0} \subset \Pi=G_{K, S}$ of finite index is again of the form $G_{K_{0}, S_{0}}$ for some finite field extension $K_{0} / K$ and the set of continuous homomorphism $\left.\operatorname{Hom}_{\text {cont }}\left(G_{K_{0}, S_{0}}, \mathbb{Z} / p \mathbb{Z}\right)=\operatorname{Hom}_{\text {cont }}\left(G_{K_{0}, S_{0}}^{\text {ab }}, \mathbb{Z} / p \mathbb{Z}\right)\right)$.
We may also take $\Pi=G_{K}$, the Galois group of an algebraic closure of any local field $K$.

### 1.2 Cohomology

Let $G$ be a finite group, and let $M$ be an abelian group on which $G$ acts. We denote the action of $\sigma \in G$ on $m$ by sending $m \in M$ to $m^{\sigma}$. Then we say that $M$ is a (right)
$G$-module if the action of $G$ on $M$ satisfies:

$$
m^{1}=m, \quad\left(m+m^{\prime}\right)^{\sigma}=m^{\sigma}+m^{\prime \sigma}, \quad\left(m^{\sigma}\right)^{\tau}=m^{\sigma \tau}
$$

Let now $M$ and $N$ be $G$-modules. In particular a $G$-module homomorphism is a homomorphism $\phi: M \rightarrow N$ commuting with the action of $G$, i.e.:

$$
\phi\left(m^{\sigma}\right)=\phi(m)^{\sigma} \quad \text { for all } m \in M, \text { for all } \sigma \in G
$$

For a given $G$-module $M$, we are often interested in calculating the largest submodule of $M$ on which $G$ acts trivially.

Definition 1.7. The $0^{\text {th }}$ cohomology group of the $G$-module $M$, which is denoted by $M^{G}$ or $H^{0}(G, M)$, is the set:

$$
H^{0}(G, M)=\left\{m \in M: m^{\sigma}=m \quad \forall \sigma \in G\right\}
$$

i.e. it is the submodule of $M$ consisting of all $G$-invariant elements.

Let:

$$
0 \longrightarrow P \xrightarrow{\phi} M \xrightarrow{\psi} N \longrightarrow 0
$$

be an exact sequence of $G$-modules (so $\phi$ and $\psi$ are $G$-module homomorphisms with $\phi$ injective, $\psi$ surjective, and $\operatorname{Im}(\phi)=\operatorname{ker}(\psi))$. It is easy to check that taking $G$-invariants gives an exact sequence:

$$
0 \longrightarrow P^{G} \xrightarrow{\phi} M^{G} \xrightarrow{\psi} N^{G}
$$

but the map on the right may not be surjective. In order to measure this lack of surjectivity, we make the following definitions:

Definition 1.8. Let $M$ be a $G$-module. The group of 1-cochains (from $G$ to $M$ ) is defined
by:

$$
C^{1}(G, M)=\{\text { maps } \xi: G \rightarrow M\}
$$

The group of $\mathbf{1}$-cocycles (from $G$ to $M$ ) is given by:

$$
Z^{1}(G, M)=\left\{\xi \in C^{1}(G, M): \xi_{\sigma \tau}=\xi_{\sigma}^{\tau}+\xi_{\tau} \forall \sigma, \tau \in G\right\}
$$

The group of 1-coboundaries (from $G$ to $M$ ) is defined by:

$$
B^{1}(G, M)=\left\{\xi \in C^{1}(G, M): \exists m \in M \text { s.t. } \xi_{\sigma}=m^{\sigma}-m \forall \sigma \in G\right\}
$$

It is easy to check that $B^{1}(G, M) \subset Z^{1}(G, M)$. The $\mathbf{1}^{\text {st }}$ cohomology group of the $G$-module $M$ is the quotient group:

$$
H^{1}(G, M)=\frac{Z^{1}(G, M)}{B^{1}(G, M)}
$$

In other words, $H^{1}(G, M)$ is the group of 1 -cocycles $\xi: G \rightarrow M$ modulo the equivalence relation that two cocycles are identified if their difference has the form $\sigma \mapsto m^{\sigma}-m$ for some $m \in M$.

Remark 1.1. Notice that if the action of $G$ on $M$ is trivial, then:

$$
H^{0}(G, M)=M \quad \text { and } \quad H^{1}(G, M)=\operatorname{Hom}(G, M)
$$

Proposition 1.1. Let

$$
0 \longrightarrow P \xrightarrow{\phi} M \xrightarrow{\psi} N \longrightarrow 0
$$

be an exact sequence of G-modules. Then there is a long exact sequence:

$$
\begin{gathered}
H^{0}(G, P) \longrightarrow H^{0}(G, M) \longrightarrow H^{0}(G, N) \\
\longrightarrow H^{1}(G, P) \longrightarrow H^{1}(G, M) \longrightarrow H^{1}(G, N)
\end{gathered}
$$

where the connecting homomorphism $\delta$ is defined as follows.
Let $n \in H^{0}(G, N)=N^{G}$ and choose an $m \in M$ such that $\psi(m)=n$ and define a cochain $\xi \in C^{1}(G, M)$ by:

$$
\xi_{\sigma}=m^{\sigma}-m
$$

Then the values of $\xi$ are in $P$, so $\xi \in Z^{1}(G, P)$, and we define $\delta(n)$ to be the cohomology class in $H^{1}(G, P)$ of the 1-cocycle $\xi$.

Suppose now that $H$ is a subgroup of $G$. Then any $G$-module is automatically an $H$ module. Further, if $\xi: G \rightarrow M$ is a 1-cochain, then by restricting the domain of $\xi$ to $H$, we obtain an $H$-to- $M$ cochain. It is clear that this process takes cocycles to cocycles and coboundaries to coboundaries, so in this way we obtain a restriction homomorphism:

$$
\text { Res : } H^{1}(G, M) \rightarrow H^{1}(H, M)
$$

Suppose further that $H$ is a normal subgroup of $G$. Then the submodule $M^{H}$ of $M$ consisting of elements fixed by $H$ has a natural structure as a $G / H$-module.

Let $\xi: G / H \rightarrow M^{H}$ be a 1-cochain from $G / H$ to $M^{H}$. Then composing with the projection $G \rightarrow G / H$ and with the inclusion $M^{H} \subset M$ gives a $G$-to- $M$ cochain:

$$
G \longrightarrow G / H \xrightarrow{\xi} M^{H} \subset M
$$

Again it is easy to see that if $\xi$ is a cocycle or coboundary, then the new $G$-to- $M$ cochain has the same property. This gives an inflation homomorphism:

$$
\text { Inf }: H^{1}\left(G / H, M^{H}\right) \rightarrow H^{1}(G, M)
$$

Proposition 1.2. Let $M$ be a $G$-module and let $H$ be a normal subgroup of $G$. Then the following sequence (Inflation-Restriction Sequence) is exact:

$$
0 \longrightarrow H^{1}\left(G / H, M^{H}\right) \xrightarrow{\mathrm{Inf}} H^{1}(G, M) \xrightarrow{\text { Res }} H^{1}(H, M)
$$

## Chapter 2

## The modularity problem

In this chapter we will introduce the Modularity Theorem and we will recall some background material about the two main ingredients on this problem: elliptic curves and modular forms.

A genereal reference for the results shown in this chapter is [15] and [5]. For the modular forms' section we will refer also to [13], [8], [9], while a good reference for the last section is [4].

### 2.1 Elliptic curves

### 2.1.1 Definitions

Definition 2.1. An elliptic curve is a pair $(E, O)$, where $E$ is a nonsingular curve of genus one and $O \in E$. The elliptic curve $E$ is defined over $K$, written $E / K$, if $E$ is defined over $K$ as a curve and $O \in E(K)$.

If $E / K$ is an elliptic curve, then $E$ can be realized in the projective plane by a Weierstrass equation, i.e. an equation of the form:

$$
Y^{2} Z+a_{1} X Y Z+a_{3} Y Z^{2}=X^{3}+a_{2} X^{2} Z+a_{4} X Z^{2}+a_{6} Z^{3}
$$

where the distinguished point is $O=[0,1,0]$ and $a_{1}, \ldots, a_{6} \in \bar{K}$.
Using non-homogeneous coordinates $x=X / Y$ and $y=Y / Z$ we get:

$$
E: y^{2}+a_{1} x y+a_{3} y=x^{3}+a_{2} x^{2}+a_{4} x+a_{6}
$$

If $\operatorname{char}(\bar{K}) \neq 2$ we can simplify the equation by completing the square, and the substitution:

$$
y \mapsto \frac{1}{2}\left(y-a_{1} x-a_{3}\right)
$$

gives an equation of the form:

$$
E: y^{2}=4 x^{3}+b_{2} x^{2}+2 b_{4} x+b_{6}
$$

where:

$$
b_{2}=a_{1}^{2}+4 a_{4}, \quad b_{4}=2 a_{4}+a_{1} a_{3}, \quad b_{6}=a_{3}^{2}+4 a_{6}
$$

We also define quantities:

$$
\begin{aligned}
& b_{8}=a_{1}^{2} a_{6}+4 a_{2} a_{6}-a_{1} a_{3} a_{4}+a_{2} a_{3}^{2}-a_{4}^{2} \\
& c_{4}=b_{2}^{2}-24 b_{4} \\
& c_{6}=-b_{2}^{3}+36 b_{2} b_{4}-216 b_{6} \\
& \Delta=-b_{2}^{2} b_{8}-8 b_{4}^{3}-27 b_{6}^{2}+9 b_{2} b_{4} b_{6} \\
& j=\frac{c_{4}^{3}}{\Delta} \\
& \omega=\frac{d x}{2 y+a_{1} x+a_{3}}=\frac{d y}{3 x^{2}+2 a_{2} x+a_{4}-a_{1} y}
\end{aligned}
$$

It is easy to check that they satisfy the relations:

$$
4 b_{8}=b_{2} b_{6}-b_{4}^{2} \quad \text { and } \quad 1728 \Delta=c_{4}^{3}-c_{6}^{2}
$$

If further $\operatorname{char}(\bar{K}) \neq 2,3$, then the substitution:

$$
(x, y) \mapsto\left(\frac{x-3 b_{2}}{36}, \frac{y}{108}\right)
$$

eliminates the $x^{2}$ term, yielding the simpler equation:

$$
E: y^{2}=x^{3}-27 c_{4} x-54 c_{6}
$$

Definition 2.2. The quantity $\Delta$ is the discriminant of the Weierstrass equation, the quantity $j$ is the $\boldsymbol{j}$-invariant of the elliptic curve, and $\omega$ is the invariant differential associated to the Weierstrass equation.

Remark 2.1. The $j$-invariant is an invariant of the isomorphism class of the curve, and does not depend on the particular equation chosen (so $j$ only depends on $E$ and will be denoted by $j_{E}$ ). For algebraically closed fields the converse is true.

Let now $P=\left(x_{0}, y_{0}\right)$ be a point satisfying a Weierstrass equation:

$$
f(x, y)=y^{2}+a_{1} x y+a_{3} y-x^{3}-a_{2} x^{2}-a_{4} x-a_{6}=0
$$

and assume that $P$ is a singular point on the curve $f(x, y)=0$.
Then we get:

$$
\frac{\partial f}{\partial x}(P)=\frac{\partial f}{\partial y}(P)=0
$$

It follows that there are $\alpha, \beta \in \bar{K}$ such that the Taylor series expansion of $F(x, y)$ at $P$ has the form:

$$
f(x, y)-f\left(x_{0}-y_{0}\right)=\left(\left(y-y_{0}\right)-\alpha\left(x-x_{0}\right)\right)\left(\left(y-y_{0}\right)-\beta\left(x-x_{0}\right)\right)-\left(x-x_{0}\right)^{3}
$$

Definition 2.3. With notation as above, the singular point $P$ is a node if $\alpha \neq \beta$. In this case, the lines:

$$
y-y_{0}=\alpha\left(x-x_{0}\right) \quad \text { and } \quad y-y_{0}=\beta\left(x-x_{0}\right)
$$

are the tangent lines at $P$. Conversely, if $\alpha=\beta$, we say that $P$ is a $\boldsymbol{c u s p}$, in which case the tangent line at $P$ is given by:

$$
y-y_{0}=\alpha\left(x-x_{0}\right)
$$

Proposition 2.1. We have the following results about elliptic curves:
(a) The curve given by a Weierstrass equation satisfies:
(i) It is nonsingular if and only if $\Delta \neq 0$
(ii) It has a node if and only if $\Delta=0$ and $c_{4} \neq 0$
(iii) It has a cusp if and only if $\Delta=c_{4}=0$

In cases (ii) and (iii), there is only one singular point.
(b) Two elliptic curves are isomorphic over $\bar{K}$ if and only if they both have the same $j$-invariant
(c) Let $j_{0} \in \bar{K}$. There exists an elliptic curve defined over $K\left(j_{0}\right)$ whose $j$-invariant is equal to $j_{0}$

Proposition 2.2. If a curve $E$ given by a Weierstrass equation is singular, then there exists a rational map $\phi: E \rightarrow \mathbb{P}^{1}$ of degree one.

An algebraic map between two elliptic curves which sends the distinguished point of one to the distinguished point of the other is automatically a morphism of algebraic groups.

Definition 2.4. Let $E_{1}, E_{2}$ be elliptic curves. An isogeny from $E_{1}$ to $E_{2}$ is a morphism $\phi: E_{1} \rightarrow E_{2}$ satisfying $\phi(O)=O$.

Two elliptic curves are isogenous if there is an isogeny from $E_{1}$ to $E_{2}$ with $\phi\left(E_{1}\right) \neq\{O\}$.

We can now consider an elliptic curve $E$ given by a Weierstrass equation: $E \subset \mathbb{P}^{2}$ consists of the points $P=(x, y)$ satisfying the Weierstrass equation, together with the point $O=[0,1,0]$ at infinity. Now, if $L \subset \mathbb{P}^{2}$ is a line, $L$ intersects $E$ at exactly three points, say $P, Q, R$.

We define a composition law $\oplus$ on $E$ by the following rule. Let $P, Q \in E$, let $L$ be the line through $P$ and $Q$, and let $R$ be the third point of intersection of $L$ with $E$. Let $L^{\prime}$ be the line through $R$ and $O$. Then $L^{\prime}$ intersects $E$ at $R, O$ and a third point, that we denote by $P \oplus Q$.

Proposition 2.3. The composition law $\oplus$ makes $E$ into an abelian group with identity element $O$. Moreover, if $E$ is defined over $K$, then:

$$
E(K)=\left\{(x, y) \in K^{2}: y^{2}+a_{1} x y+a_{3} y=x^{3}+a_{2} x^{2}+a_{4} x+a_{6}\right\} \cup\{O\}
$$

is a subgroup of $E$.
This means that an elliptic curve $E / K$ has a natural structure of a commutative algebraic group with the distinguished $K$-rational point as the identity element.

### 2.1.2 Elliptic curves over $\mathbb{Q}_{p}$

Suppose that $E$ is an elliptic curve defined over the $p$-adic field $\mathbb{Q}_{p}$. There is an equation $W^{\text {min }}$ for $E$ such that all the coefficients are in $\mathbb{Z}_{p}$ and $|\Delta|$ is minimal among all such equations for $E$. The associated discriminant depends only on $E$, it is denoted $\Delta_{E}^{\min }$ and it divides the discriminant of every possible equation for $E$ with coefficients in $\mathbb{Z}_{p}$.

Definition 2.5. If $\bar{E}$ is a smooth curve we say that $E$ has a good reduction at $p$. If $\bar{E}$ has a unique singular point which is a node we say that $E$ has multiplicative reduction at $p$. Otherwise $\bar{E}$ has a unique singular point which is a cusp and we say that $E$ has additive reduction at $p$.

If $E$ has good or multiplicative reduction we say that it has semi-stable reduction at $p$, or simply that $E$ is semistable.

If $E$ has a good reduction, then $p$ does not divide $\Delta_{E}^{\text {min }}$, and the reduction $\bar{E}$ is an elliptic curve over $\mathbb{F}_{p}$.

If $q$ is any power of $p$, and $\mathbb{F}_{q}$ is the field with $q$ elements, we define the integer $N_{q}$ to be the number of solutions to the equation $W^{\text {min }}$ in the projective plane $\mathbb{P}^{2}\left(\mathbb{F}_{q}\right)$. Thus $N_{q}$ is the order of the finite group $\bar{E}\left(\mathbb{F}_{q}\right)$. We define the integer $a_{q}$ by the formula:

$$
a_{q}=q+1-N_{q}
$$

The integers $a_{q}$ are completely determined by $a_{p}=\operatorname{Tr}\left(\rho\left(\operatorname{Frob}_{p}\right)\right)$ as shown in the relation:

$$
\left(1-a_{p} p^{-s}+p^{1-2 s}\right)^{-1}=1+a_{p} p^{-s}+a_{p^{2}} p^{-2 s}+a_{p^{3}} p^{-3 s}+\ldots
$$

Definition 2.6. We define:

$$
L(E / \mathbb{Q}-p, s)=\left(1-a_{p} p^{-s}+p^{1-2 s}\right)^{-1}
$$

to be the L-function associated to $E$ over $\mathbb{Q}_{p}$.
Definition 2.7. We say that $E$ as good ordinary reduction if $p$ does not divide $a_{p}$, supersingular reduction otherwise.

When $E$ has good reduction at $p$, we define its local conductor at $p$ to be $m_{p}(E)=0$.

If $E$ has multiplicative reduction at $p$ we can use $p$-adic analytic methods to describe $j$ and to define the Tate's $p$-adic period associated to $E$ over $\mathbb{Q}_{p}$.

Definition 2.8. We say that $E$ has split (resp. non-split) multiplicative reduction at $p$ if the two tangent lines to the node on $\bar{E}\left(\mathbb{F}_{p}\right)$ have slopes defined over $\mathbb{F}_{p}\left(\right.$ resp. $\left.\mathbb{F}_{p^{2}}\right)$.

Definition 2.9. We define the L-function $L\left(E / \mathbb{Q}_{p}, s\right)$ to be:

$$
L\left(E / \mathbb{Q}_{p}, s\right)= \begin{cases}\left(1-p^{-s}\right)^{-1} & \text { if } E \text { has split reduction } \\ \left(1+p^{-s}\right)^{-1} & \text { if } E \text { has non-split reduction }\end{cases}
$$

The conductor $m_{p}(E)$ is defined to be 1 in both cases.

If $E$ has additive reduction at $p$, we define:
Definition 2.10. The L-function of $E$ is:

$$
L\left(E / \mathbb{Q}_{p}, s\right)=1
$$

For $p>3$ the conductor $m_{p}(E)$ is set to be 2 .

### 2.1.3 Elliptic curves over $\mathbb{Q}$

Let $E$ be an elliptic curve defined over $\mathbb{Q}$.
We define the global conductor by $N_{E}=\Pi_{p} p^{m_{p}(E)}$.
The curve $E$ is said to be semi-stable if it is semi-stable over all $p$-adic fields $\mathbb{Q}_{p}$.
Using the fact that $\mathbb{Q}$ has class number 1 , one can show $E$ has a global minimal Weierstrass model $W^{\text {min }}$ which gives the equation of a minimal Weierstrass model over each $\mathbb{Q}_{p}$. The associated discriminant, denoted $\Delta_{E}^{\min }$, depends only on $E$. The associated differential, denoted $\omega_{E}^{\text {Neron }}$, is called the Néron differential.

Theorem 2.4 (Mordell-Weil Theorem). The group $E(\mathbb{Q})$ is a finitely generated abelian group. Hence:

$$
E(\mathbb{Q}) \cong T \oplus \mathbb{Z}^{r}
$$

where $T$ is the finite torsion subgroup of $E(\mathbb{Q})$, and $r \geq 0$ is the rank of $E$ over $\mathbb{Q}$.
In [11], Mazur proved the following:
Theorem 2.5. If $E / \mathbb{Q}$ is an elliptic curve, then its torsion group is isomorphic to one of the following possibilities:

$$
\mathbb{Z} / n \mathbb{Z}, 1 \leq n \leq 10, n=12, \quad \mathbb{Z} / 2 n \mathbb{Z} \times \mathbb{Z} / 2 \mathbb{Z}, 1 \leq n \leq 4
$$

Many of the deep results on $E(\mathbb{Q})$ and $r$ are based on the relation with the $L$-functions.

Definition 2.11. We define the global $L$-function of the complex variable $s$ by:

$$
L(E / \mathbb{Q}, s)=\Pi_{p} L\left(E / \mathbb{Q}_{p}, s\right)
$$

### 2.2 Modular forms

### 2.2.1 Definitions

Given the upper half complex plane $\mathcal{H}$ and the group $S L_{2}(\mathbb{R})$, we can make $S L_{2}(\mathbb{R})$ act on $\mathbb{C}^{*}=\mathbb{C} \cup\{\infty\}$ in this way:

$$
g z=\frac{a z+b}{c z+d} \quad \text { for } \quad g=\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \in \mathrm{GL}_{2}(\mathbb{R}), \quad z \in \mathbb{C}^{*}
$$

We get:

$$
\operatorname{Im}(g z)=\frac{\operatorname{Im}(z)}{|c z+d|^{2}}
$$

i.e. $\mathcal{H}$ is stable under the action of $S L_{2}(\mathbb{R})$.

We have that the element $-\mathbb{1}=\left(\begin{array}{cc}-1 & 0 \\ 0 & -1\end{array}\right) \in \mathrm{GL}_{2}(\mathbb{R})$ acts trivially on $\mathcal{H}$, then we can think as it is the projective special linear group over $\mathbb{R}$ which operates.

Definition 2.12. $G=S L_{2}(\mathbb{R}) / \mp 1$ is the Modular Group.
Let $S=\left(\begin{array}{cc}0 & -1 \\ 1 & 0\end{array}\right), T=\left(\begin{array}{ll}1 & 1 \\ 0 & 1\end{array}\right), S, T$ in $G$.
Theorem 2.6. The group $G$ is generated by $S$ and $T$.
We can now consider the subset $D$ of $\mathcal{H}$ formed of all points $z$ such that $|z|>1$ and $|\operatorname{Re}(z)| \leq \frac{1}{2}$ :

$$
D=\left\{z=x+i y:|z|>1,|x| \leq \frac{1}{2}\right\}
$$

It is possible to show that $D$ is a fundamental domain for the action of $G$ on $\mathcal{H}$. More precisely:

Theorem 2.7. (1) $\forall z \in \mathcal{H}, \exists g \in G: g z \in D$
(2) Suppose that two distinct point $z, z^{\prime} \in D$ are congruent mod $G$. Then: $\operatorname{re}(z)=\mp \frac{1}{2}$ and $z=z^{\prime}+1$ or $|z|=1$ and $z^{\prime}=-\frac{1}{z}$
(3) Let $z \in D$ and let $\operatorname{Stab}(z)=\{g \mid g \in G, g z=z\}$ the stabilizer of $z$ in $G$. We get $\operatorname{Stab}(z)=1$ except in the following three cases:
$-z=i$, in which case $\operatorname{Stab}(z)$ is the group of order 2 generated by $S$
$-z=e^{2 \pi i / 3}$, in which case $\operatorname{Stab}(z)$ is the group of order 3 generated by ST
$-z=e^{\pi i / 3}$, in which case $\operatorname{Stab}(z)$ is the group of order 3 generated by TS

Corollary 2.8. By (1) and (2) follows that the canonical map from $D$ to $\mathcal{H} / G$ is surjective and its restriction to the interior of $D$ is injective.

We can now state the following definition:

Definition 2.13. Let $k$ be an integer, we say that a function $f$ is weakly modular of weight $2 k$ if f is meromorphic on $\mathcal{H}$ and:

$$
f(z)=(c z+d)^{-2 k} f\left(\frac{a z+b}{c z+d}\right) \quad \forall\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \in S L_{2}(\mathbb{Z})
$$

Proposition 2.9. Let $f$ be meromorphic on $\mathcal{H}$, $f$ is weakly modular of weight $2 k$ if and only if it satisfies the two relations:
(a) $f(z+1)=f(z)$
(b) $f(-1 / z)=z^{2 k} f(z)$

Definition 2.14. A weakly modular function is a modular function if it is meromorphic at infinity. Moreover, we say that a modular function is of level N if it is a meromorphic funtion on $\mathcal{H}$ invariant under the group:

$$
\Gamma(N)=\left\{\left.\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \right\rvert\, a \equiv d \equiv 1, b \equiv c \equiv 0 \quad \bmod N\right\}
$$

Definition 2.15. A modular function which is holomorphic everywhere is called a modular form. If such a form is zero at infinity it is called a cusp form.

A modular form of weight $2 k$ is thus given by a series:

$$
f(z)=\sum_{n=0} a_{n} q^{n}=\sum_{n=0} a_{n} e^{2 \pi i n z}
$$

which converges for $|q|<1$ and verifies the identity $(b)$ above. It is a cusp form if $a_{0}=0$.

### 2.2.2 The $L$-function associated to a cusp form

Let $f$ be a cusp form on

$$
\Gamma_{1}(N)=\left\{\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \left\lvert\,\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \equiv\left(\begin{array}{ll}
1 & * \\
0 & 1
\end{array}\right) \quad \bmod N\right.\right\}
$$

with Fourier expansion at $i \infty$ given by $\sum_{n=0}^{+\infty} a_{n} q^{n}$.

Definition 2.16. The $L$-function associated to $f$ is defined by the formula:

$$
L(f, s)=\sum_{n=1}^{+\infty} a_{n} n^{-s}
$$

It is possible to prove that the infinite sum defining $L(f, s)$ converges absolutely in the right half-plane $\operatorname{Re}(s)>\frac{3}{2}$.

### 2.2.3 Hecke Theory

Suppose $\Gamma=\Gamma_{1}(N)$, we start by recalling the definition of diamond operator.

Definition 2.17. For $d \in(\mathbb{Z} / N \mathbb{Z})^{\times}$, we denote by $\langle d\rangle$ the diamond operator, which sends an elliptic curve $(E, P)$ to the pair $(E, d P)$, where $P$ is a point on $E$ of exact order $N$.

Suppose $\Gamma_{1}(N) \subset \Gamma \subset \Gamma_{0}(N)$.

Definition 2.18. If $p$ is a prime not dividing the level $N$, we define the Hecke operator $T_{p}$ on the space of cusp forms of weight 2 on $\Gamma, S_{2}(k)$ as:

$$
T_{p}(f)=\frac{1}{p} \sum_{1=0}^{p-1} f\left(\frac{\tau+i}{p}\right)+p\langle p\rangle f(p \tau)
$$

If $p$ divides $N$, then we define the Hecke operator $U_{p}$ analogously:

$$
U_{p}(f)=\frac{1}{p} \sum_{1=0}^{p-1} f\left(\frac{\tau+i}{p}\right)
$$

It is possible to check that the Hecke operators of the form $T_{p}$ or $U_{q}$ commute with each other and with the diamond operator. We denote by $\mathbb{T}$ the subring of $\operatorname{End}_{\mathbb{C}}\left(S_{2}(\Gamma)\right)$ generated over $\mathbb{C}$ by all the Hecke operators $T_{p}$ for $p \nmid N, U_{q}$ for $q \mid N$, and $\langle d\rangle$ acting on $S_{2}(\Gamma)$.

Definition 2.19. A modular form $f$ is an eigenform if it is a simultaneous eigenvector of all the Hecke operators in $\mathbb{T}$, i.e. if there exists a $\mathbb{C}$-algebra homomorphism $\lambda: \mathbb{T} \rightarrow \mathbb{C}$ such that $T f=\lambda(T) f$, for all $T \in \mathbb{T}$.

Definition 2.20. We define the old subspace of $S_{2}(\Gamma)$ to be the space spanned by those functions which are of the form $g(a z)$ where $g$ is in $S_{2}\left(\Gamma_{1}(M)\right)$ for some $M<N$ and $a M$ divides $N$. We define the new subspace of $S_{2}(\Gamma)$ to be the orthogonal complement of the old subspace with respect to the Petersson scalar product (see [5] for the details). A normalized eigenform in the new subspace is called a newform of level $N$.

### 2.3 Galois representations

We can consider the surjection $\rho: G_{\mathbb{Q}_{p}} \rightarrow G_{\mathbb{F}_{p}}$ where $\mathbb{Q}_{p}$ is the $p$-adic field and $\mathbb{F}_{p}$ is a finite field.

Definition 2.21. We define the inertia group $I_{p}$ to be the kernel of the morphism $\rho$ above.
Definition 2.22. A d-dimensional representation of $G_{\mathbb{Q}}$ is a continuous homomorpshim $G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{d}(K)$, where $K$ is any topological field.

It is possible to give a complete description of the one-dimensional representations of $G_{\mathbb{Q}}$. Definition 2.23. We say that a representation $\rho$ of $G_{\mathbb{Q}}$ is unramified at $p$ if it is trivial on the intertia group $I_{p}$, it is ramified otherwise.

Definition 2.24. We can distinguish three types of representations:

- Artin representations: continuous representations $G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{d}(\mathbb{C})$. Since all compact totally disconnected subgroups of $\mathrm{GL}_{d}(\mathbb{C})$ are finite, Artin representations have finite image. Hence they are semi-simple and they are unramified at all but finitely many primes.
- Mod $\ell$ representations: continuous representations $G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{d}(k)$ where $k$ is a finite field of characteristic $\ell$. Like Artin representations, they are unramified at all but finitely many primes.
- $\ell$-adic representations: continuous representations $G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{d}(K)$ where $K$ is a finite extension of $\mathbb{Q}_{\ell}$. We require an $\ell$-adic representation to be unramified at all but finitely many primes

### 2.3.1 Representations associated to elliptic curves

Let $E[n](\overline{\mathbb{Q}})$ be the group of $n$-torsion points on $E(\overline{\mathbb{Q}})$, we know that $E[n](\overline{\mathbb{Q}}) \cong(\mathbb{Z} / n \mathbb{Z})^{2}$. Furthermore, $E[n](\overline{\mathbb{Q}})$ carries a natural action of $G_{\mathbb{Q}}$ and so we get a representation (defined up to conjugation):

$$
\bar{\rho}_{E, n}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}(\mathbb{Z} / n \mathbb{Z})
$$

If $\ell$ is a prime different from the characteristic of $\mathbb{Q}$, then we set $\mathcal{T}_{l} E=\underset{\rightleftarrows}{\lim } E\left[l^{n}\right](\overline{\mathbb{Q}})$, which is non canonically ismorphic to $\mathbb{Z}_{\ell}^{2}$. Since it has a natural continuous action of $G_{\mathbb{Q}}$, we get a representation:

$$
\rho_{E, l}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathbb{Z}_{\ell}\right)
$$

We note that $\rho_{E, \ell^{n}} \cong \rho_{E, \ell} \bmod \ell^{n}$, where $\rho_{E, \ell^{n}}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathbb{Z} / \ell^{n} \mathbb{Z}\right)$.
It is possible to show that the representations associated to elliptic curves (i.e. the associated Tate Modules) have the following properties (see [5] for the details)

- Global properties:
(a) The representation $\rho_{E, \ell}$ is absolutely irreducible for all $\ell$. For fixed $E, \bar{\rho}_{E, \ell}$ is absolutely irreducible for all but finitely many $\ell$.
(b) If $E$ does not have complex multiplication then $\rho_{E, \ell}$ (and hence $\bar{\rho}_{E, \ell}$ is surjective for all but finitely many $\ell$ ).

If $E / \mathbb{Q}$ is an elliptic curve, we get:
(c) If $\ell>163$ is a prime, then $\bar{\rho}_{E, \ell}$ is irreducible
(d) If $E$ is semistable then $\bar{\rho}_{E, \ell}$ is irreducible for $\ell>7$
(e) If $E$ is semistable and $\bar{\rho}_{E, 2}$ is trivial, then $\bar{\rho}_{E, \ell}$ is irreducible for $\ell>3$.

- Local properties:

Suppose $E$ has good reduction at $p$ :
(a) If $\ell \neq p$, then $\rho_{E, \ell}$ is unramified at $p$, and we have the formula:

$$
\operatorname{tr}_{\rho_{E, \ell}}\left(\operatorname{Frob}_{p}\right)=p+1-\# \bar{E}_{p}\left(\mathbb{F}_{p}\right)
$$

In particular, $\operatorname{tr}_{\rho_{E, \ell}}\left(\right.$ Frob $\left._{p}\right)$ belongs to $\mathbb{Z}$ and is independent of $\ell \neq p$.

### 2.3.2 Representations associated to modular forms

Suppose $f=\sum a_{n}(f) q^{n}$ is a newform of weight two and level $N_{f}$. Let $K_{f}$ denote the number field in $\mathbb{C}$ generated by the Fourier coefficients $a_{n}(f)$. Using a construction of Shimura, we can associate to $f$ an abelian variety $A_{f}$ of dimension $\left[K_{f}: \mathbb{Q}\right]$. An appropriate choice of the basis of the Tate module associated to each prime $\ell$ provides a representation:

$$
G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(K_{f} \otimes \mathbb{Q}_{\ell}\right)
$$

## $\ell$-adic representations

Let $\ell$ be a fixed prime and $K$ a finite extension of $\mathbb{Q}_{\ell}$ and let $K_{f}^{\prime}$ be the $K$-algebra in $\overline{\mathbb{Q}}_{\ell}$ generated by the Fourier coefficients of $f$. We fix the embeddings: $\overline{\mathbb{Q}} \hookrightarrow \mathbb{Q}_{\ell}$ and $\bar{Q} \hookrightarrow \mathbb{C}$. We define:

$$
\rho_{f}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(K_{f}^{\prime}\right)
$$

as the pushforward of $G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(K_{f} \otimes \mathbb{Q}_{\ell}\right)$ by the natural map $K_{f} \otimes \mathbb{Q}_{\ell} \rightarrow K_{f}^{\prime}$. The $\ell$-adic representation $\rho: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(K^{\prime}\right)$ has the following properties (see [5] for the details):
(a) If $p \nmid N \ell$ then $\rho$ is unramified at $p$ and $\rho\left(\operatorname{Frob}_{p}\right)$ has characteristic polynomial $X^{2}-$ $a_{p} X+p \psi(p)$, where $\psi$ is the homomorphism $(\mathbb{Z} / N \mathbb{Z})^{\times} \rightarrow K_{f}^{\times}$defined by mapping $d$ to the eigenvalue of $\langle d\rangle$ on $f$.
(b) $\operatorname{det}(\rho)$ is the product of $\psi_{f}^{\prime}: G_{\mathbb{Q}} \rightarrow \operatorname{Gal}\left(\mathbb{Q}\left(\xi_{N_{f}}\right) / \mathbb{Q}\right) \rightarrow\left(K_{f}^{\prime}\right)^{\times}$with the $\ell$-adic cyclotomic character $\epsilon$, and $\rho(c)$ is conjugate to $\left(\begin{array}{cc}1 & 0 \\ 0 & -1\end{array}\right)$
(c) $\rho$ is absolutely irreducible
(d) The conductor $N(\rho)$ is the prime-to- $\ell$-part of $N$.
(e) Suppose that $p \neq \ell$ and $p \| N$. Let $\chi$ denote the unramified character $G_{p} \rightarrow\left(K^{\prime}\right)^{\times}$ satisfying $\chi\left(\operatorname{Frob}_{p}\right)=a_{p}$. If $p$ does not divide the conductor of $\psi$, then $\left.\rho\right|_{G_{p}}$ is of the
form: $\left(\begin{array}{cc}\chi \epsilon & * \\ 0 & \chi\end{array}\right)$ If $p$ divides the conductor of $\psi$, then $\left.\rho\right|_{G_{p}}$ is of the form:

$$
\left.\chi^{-1} \epsilon \psi^{\prime}\right|_{G_{p}} \oplus \chi
$$

(f) If $\ell \nmid 2 N$, then $\left.\rho\right|_{G_{\ell}}$ is good. Moreover $\rho \mid G_{p}$ is ordinary if and only if $a_{\ell}$ is a unit in the ring of integers of $K^{\prime}$, in which case $\rho_{I_{\ell}}\left(\mathrm{Frob}_{\ell}\right)$ is the unit root of the polynomial $X^{2}-a_{\ell} X+\ell \psi(\ell)$.
(g) If $\ell$ is odd and $\ell \| N$, but the conductor of $\psi$ is not divisible by $\ell$, then $\left.\rho\right|_{G_{\ell}}$ is ordinary and $\rho_{I_{\ell}}\left(\operatorname{Frob}_{\ell}\right)=a_{\ell}$.

## Mod $\ell$ representations

Keeping the same notation, we define:

$$
\bar{\rho}_{f}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(k_{f}\right)
$$

to be the semi-simplification of the reduction of $p_{f}$. The analogous of the properties stated above hold for $\bar{\rho}=\bar{\rho}_{f}$, except that:

- The representation need not be absolutely irreducible (as in $(c)$ ). However, if $\ell$ is odd, one checks using $(b)$ that $\bar{\rho}$ is irreducible if and only if it is absolutely irreducible.
- In $(d)$ one only has divisibility of the prime-to- $\ell$ part of $N_{f}$ by $N(\bar{\rho})$ in general.
- If $p$ is a prime such that $p \mid N_{f}, p \nsupseteq 1 \bmod \ell$ and $\bar{\rho}_{f}$ is unramified at $p$. Then $\operatorname{Tr}\left(\bar{\rho}_{f}\left(\operatorname{Frob}_{p}\right)\right)^{2}=(p+1)^{2}$ in $k_{f}$.

## Artin representations

The theory of Hecke operators and newforms extends to modular forms on $\Gamma_{1}(N)$ of arbitrary weight. We have the following theorem:

Theorem 2.10. If $g=\sum a_{n}(g) q^{n}$ is a newform of weight one, level $N_{g}$ and character $\psi_{g}$, then there is an irreducible Artin representation:

$$
\rho_{g}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}(\mathbb{C})
$$

of conductor $N_{g}$ with the following property: if $p \nmid N_{g}$, then the characteristic polynomial of $\rho_{g}\left(\operatorname{Frob}_{p}\right)$ is $X^{2}-a_{p}(g) X+\psi_{g}(p)$.

### 2.4 The Shimura-Taniyama conjecture

### 2.4.1 The conjecture

The Shimura-Taniyama conjecture, or the modularity conjecture, announced a deep connection between elliptic curves over the rational numbers and modular forms. There are several equivalent formulations of this conjecture which we will now present.

## 1. Geometric formulation of the Shimura-Tanyama conjecture.

Let $E$ be an elliptic curve over $\mathbb{Q}$, then there exists a finite map $\phi: X_{0}(N) \rightarrow E$ defined over $\mathbb{Q}$ for some modular curve $X_{0}(N)$. More precisely, the integer $N$ may be taken to be the conductor of $E / \mathbb{Q}$.

If this happens we say that the elliptic curve is modular and we call $\phi$ a modular parametrization.
2. Formulation of the Shimura-Tanyama conjecture in terms of $L$-functions.

The elliptic curve $E$ over $\mathbb{Q}$ is modular if there exists a cuspidal eigenform $f$ of weight 2 on $\Gamma_{0}(N)$, for some $N$, such that $L(E, s)=L(f, s)$.
3. Formulation of the Shimura-Tanyama conjecture in terms of Galois representations.

Let $E$ be an elliptic curve over $\mathbb{Q}$. Then there is a cuspidal eigenform $f=\sum_{n=1}^{\infty} a_{n} q^{n}$, of weight two on $\Gamma_{0}(N)$, for some $N$ such that:

$$
\# E\left(\mathbb{F}_{p}\right)=p+1-a_{p}
$$

for all but finitely many prime integers $p$.

This last formulation can be interpreted as follows.
Let $\ell$ be a prime integer and let us recall that we denoted $G_{\mathbb{Q}}$ the absolute Galois group of $\mathbb{Q}$. We denote by:

$$
\rho_{E, \ell}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathbb{Z}_{\ell}\right)
$$

the two dimensional $\ell$-adic representation obtained from the action of $G_{\mathbb{Q}}$ on the $\ell$-adic Tate module of $E: \mathcal{T}_{\ell}(E)=\lim _{{ }_{\mathrm{n}}} E\left[\ell^{n}\right](\overline{\mathbb{Q}})$.

If we denote by $f$ the cuspidal eigenform on $\Gamma_{0}(N)$ in the third formulation of the Shimura-Tanyama conjecture and by $\rho_{f, \ell}: G_{\mathbb{Q}} \rightarrow \mathrm{GL}_{2}\left(\mathbb{Q}_{\ell}\right)$ the $\ell$-adic representation attached to $f$, then this very third formulation of the conjecture is equivalent to saying that the two Galois representations $\rho_{E, \ell}$ and $\rho_{f, \ell}$ are isomorphic for one (in fact for all) prime integer $\ell$.

In fact the Shimura-Taniyama conjecture can be generalized to a conjecture that every $\ell$-adic representation, satisfying suitable local conditions, arises from a modular form (see [7] for more details).

A first proof of the modularity conjecture was announced by A. Wiles in 1993, but after a detailed examination a serious gap was found in one part of the argument. A. Wiles and R. Taylor managed to fill in the gap completing Wiles' main argument with an additional step in 1995 ([17], [16]).

However that article did not prove the full modularity conjecture. In fact, they proved modularity only for all semistable curves over $\mathbb{Q}$, i.e. for elliptic curves $E$ over $\mathbb{Q}$ having no additive reduction. This case was enough to imply Fermat's Last Theorem and Taylor and Wiles provided a proof for it.

A proof of the full modularity conjecture was later given by Breuil, Conrad, Harris and Taylor ([2]) in 2001.

The Shimura-Taniyama conjecture is of great importance from many points of view. Firstly, it gives the analytic continuation of $L(E, s)$ for a large class of elliptic curves. Secondly, the modular curve $X_{0}(N)$ is endowed with a natural collection of algebraic points arising from the theory of complex multiplication, and the existence of a modular parametrization allows the construction of points on $E$ defined over abelian extensions of certain imaginary quadratic fields. There are various generalizations of the Shimura-Taniyama conjecture. Replacing $\mathbb{Q}$ by an arbitrary number field $K$, it predicts that an elliptic curve $E$ over $K$ is associated to an automorphic form on $\mathrm{GL}_{2}(K)$. When $K$ is totally real, such an $E$ is often uniformized by a Shimura curve attached to a suitable quaternion algebra over $K$, with exactly one split place at infinity (when $K$ is of odd degree, or when $E$ has at least one prime multiplicative reduction). In the context of function fields over finite fields, the modularity conjecture has an analogue which was established earlier by Drinfeld using methods different from those of Wiles.

### 2.4.2 The idea of the proof

Let $E$ be a semistable elliptic curve over $\mathbb{Q}$. In order to prove that the conjecture is true we can proceed in the following way:
(1) Choose a prime $p$ such that the representation modulo $p$ associated to $E$ has the following properties:
(a) $\rho_{E[p]}: G_{\mathbb{Q}, S} \rightarrow G L_{2}\left(\mathbb{F}_{p}\right)$ is modular, i.e. there is a modular eigenform $g$ of weight 2 such that its Galois representation modulo $p$ is isomorphic to $\rho_{E[p]}$;
(b) $\rho_{E[p]}$ is irreducible.

During Wiles' time it was known that one could take $p=3$, if $\rho_{E[3]}$ is irreducible because by a result of Langlands-Tunell $E[3]$ is always modular, or if $E[3]$ is not irreducible Wiles showed that $p=5$ works.
(2) Apply the deformation theory to the irreducible $(\bmod p)$ Galois representation $\rho_{E[p]}, p$ as in defined above. We obtain a universal deformation ring $R$ and a ring homomorphism $R \rightarrow \mathbb{Z}_{p}$ corresponding to the representation $T_{p}(E)$.
(3) The modular eigenform $g$ (which is only well defined modulo $p$ ) gives a ring homomorphism $\varphi_{g}: H \rightarrow \bar{F}_{p}$, where $H$ is the Hecke-algebra over $\mathbb{Z}_{p}$.

Let $\mathfrak{m}$ denote the kernel of $\varphi_{g}$, it is a maximal ideal of $H$. We localize $H$ at this maximal ideal and consider the $\mathfrak{m}$-adic completion of the localization. Denote $H_{g}$ the resulting ring.
Wiles proved that we have an isomorphism $R \cong H_{g}$.
(4) $\varphi_{g}$ composed with the inverse of this isomorphism gives an algebra homomorphism $H_{g} \rightarrow \mathbb{Z}_{p}$ which corresponds to a modular eigenform of weight 2 , whose $p$-adic Galois representation is isomorphic to $T_{p}(E)$. This shows $E$ is modular.

## Chapter 3

## Functors on Artin rings

We are now going to analyze in detail the article of Michael Schlessinger ([14]). Those results will be used for the proof of the existence of the universal deformation in the article of Mazur ([12]).

Let $\Lambda$ be a complete Noetherian local ring, $\mu$ its maximal ideal, and $k=\Lambda / \mu$ the residue field. Let $\mathbf{C}$ be the category of Artin local $\Lambda$-algebras with residue field $k$; the morphisms are the ones of local $\Lambda$-algebras, i.e. are morphisms of $\Lambda$-moduli such that the preimage of the maximal ideal is the maximal ideal and induce the identity on the residue fields.

We want to investigate when a covariant functor $F: \mathbf{C} \rightarrow$ Sets is pro-representable, i.e. when it has the form:

$$
F(A) \cong \operatorname{Hom}_{\text {local }} \Lambda-\mathrm{alg}(R, A) \quad A \in C
$$

where $R$ is a complete local $\Lambda$-Algebra, with maximal ideal $\mathfrak{m}$, such that $R / \mathfrak{m}^{n}$ is in $\mathbf{C}$ for all $n \geq 1$.

In many interesting cases $F$ is not pro-representable, but at least one may find an $R$ as above and a morphism $\phi: \operatorname{Hom}(R, \cdot) \rightarrow F(A)$ of functors such that $\operatorname{Hom}(R, A) \rightarrow F(A)$ is surjective for all $A$ in $\mathbf{C}$. The minimal $R$ with this property is called the "hull" of $F$ and it is unique up to isomorphism.

In the main theorem we will see a criterion for $F$ to have a "hull" and also a simple criterion for which this hull pro-represents $F$.

### 3.1 Schlessinger's construction

Let $\Lambda$ be as above, we define $\mathbf{C}=\mathbf{C}_{\Lambda}$ to be the catergory of Artinian local $\Lambda$-algebras having residue field $k$, i.e. "the structure morphism" $\Lambda \rightarrow A$ of such a ring $A$ induces a trivial extension of residue fields. Morpshims in $\mathbf{C}$ are local morphisms of $\Lambda$-algebras.
Let $\hat{\mathbf{C}}=\hat{\mathbf{C}}_{\Lambda}$ be the category of complete Noetherian local $\Lambda$-algebras $A$ for which $A / \mathfrak{m}^{n}$ is in $\mathbf{C}$ for all $n$. Notice that $\mathbf{C}$ is a full subcategory of $\hat{\mathbf{C}}$.

If $p: A \rightarrow B, q: C \rightarrow B$ are morphisms in $\mathbf{C}$, let $A \times{ }_{B} C$ denote the ring (in $\mathbf{C}$ ) consisting of all pairs $(a, c)$ with $a \in A, c \in C$, for which $p a=q c$, with coordinatewise multiplication and addition.
For any $A$ in $\hat{\mathbf{C}}$ we denote by $t_{A}^{*}$ the Zariski cotangent space of $A$ over $\Lambda$ :

$$
t_{A}^{*}=\mathfrak{m} / \mathfrak{m}^{2}+\mu A
$$

where $\mathfrak{m}$ is the maximal ideal of $A$.
Remark 3.1. We identify the dual of $t_{A}^{*}$ with the space of $\Lambda$-linear derivations of $A$ into $k$, $\operatorname{Der}_{\Lambda}(A, k)$, i.e. we have:

$$
\operatorname{Hom}_{k}\left(t_{A}^{*}, k\right) \cong \operatorname{Der}_{\Lambda}(A, k)
$$

So, in order to show that there exists an isomorphism between the two sets above, we have to associate to each element $\eta$ in $\operatorname{Hom}_{k}\left(t_{A}^{*}, k\right)$ a map $D_{\eta}$ from $A$ to $k$ which satisfies the conditions to be a derivation and that will be defined as:

$$
\begin{aligned}
& D_{\eta}: A \rightarrow k \\
& D_{\eta}(\lambda)=0 \quad \text { for } \lambda \in \Lambda \\
& D_{\eta}(f)=\eta([f]) \quad \text { where }[f]=f \quad \bmod \mathfrak{m}^{2}+\mu A
\end{aligned}
$$

and then extended as $\Lambda$-modules morphism.
In order to prove that this isomorphism actually exists, we first notice that $A=\underset{\leftarrow}{\lim } A / \mathfrak{m}^{n}$ (because we have a local ring which is complete), so it is enough to prove the statement for each level $A / \mathfrak{m}^{k}$ and show that the maps can be glued together in a way that respect the
projections.
In particular, it is possible to show that:

- $\forall k \geq 1, A / \mathfrak{m}_{A}^{k}$ is generated as $\Lambda$-module by $\Lambda$ and $m_{A}$
- $\forall x \in A / \mathfrak{m}_{A}^{k}, x=\lambda_{0}+\sum_{i=1}^{s} \lambda_{i} t_{i}$ for $\lambda_{0}, \lambda_{i} \in \Lambda$ and $t_{i} \in \mathfrak{m}$, we define:

$$
D_{\eta, k}: A / \mathfrak{m}^{k} \rightarrow k
$$

with:

$$
D_{\eta, k}(x)=\sum \bar{\lambda}_{i} \eta\left(\left[t_{i}\right]\right)
$$

it is a good definition and it is a derivation.

- The following diagram is commutative:

$$
\begin{array}{ccc}
A / \mathfrak{m}_{A}^{k} & \longrightarrow & k \\
\uparrow & & \uparrow \\
A / \mathfrak{m}_{A}^{k+1} & \longrightarrow & k
\end{array}
$$

and it follows that:

$$
D_{\eta}:=\left\{D_{\eta, k}\right\}:{\underset{\varliminf}{\leftrightarrows}}_{\lim } A / \mathfrak{m}^{k}=A \longrightarrow k
$$

where:

$$
D_{\eta}\left(\left(a_{k}\right)\right)=D_{\eta, k}\left(a_{k}\right)
$$

Therefore we can associate to each homomorphism a function (which is a derivation) in the way described above.

Lemma 3.1. $A$ morphism $B \rightarrow A$ in $\hat{\boldsymbol{C}}$ is surjective if and only if the induced map from $t_{B}^{*}$ to $t_{A}^{*}$ is surjective.

Proof. First, any element in $A / \mathfrak{m}^{2}$ is generated as a $\Lambda$-module, by the image of $\Lambda$ in $A$ and the maximal ideal $\mathfrak{m}$ of $A$. Thus the induced map from $\mu / \mu^{2}$ to $\mu A /\left(\mathfrak{m}^{2} \cap \mu A\right)$ (with $\mu$
maximal ideal of $\Lambda$ ) is a surjection. In fact we have that $\mu \subseteq \mathfrak{m}^{2} \cap A$ since $\mu^{2} \subseteq \mathfrak{m}^{2}$, and $\mu^{2} \subseteq \mu A$. If $x \in \mu A$, we can write $x=\alpha \cdot a$ for $\alpha \in \mu$ and $a \in A$ : now $\bar{a} \in k$, so we get $x=\alpha \cdot a=\alpha(b+y)=\alpha b+\alpha y$, where $\alpha b \in \mu \Lambda$ and $\alpha y \in \mathfrak{m}^{2} \cap \mu A$. Thus if $B \rightarrow A$ is a morphism in $\hat{\mathbf{C}}$ and $\mathfrak{m}$ and $\mathfrak{n}$ are the maximal ideals respectively of $A$ and $B$, then the rows in the following diagrams are exact:

$$
\begin{array}{ccccc}
0 \rightarrow \mu A /\left(\mu A \cap \mathfrak{m}^{2}\right) & \rightarrow \mathfrak{m} / \mathfrak{m}^{2} & \rightarrow t_{A}^{*} & \rightarrow 0 \\
\uparrow_{\alpha} & & \uparrow_{\beta} & \uparrow_{\gamma} & \\
0 \rightarrow \mu B /\left(\mu B \cap \mathfrak{n}^{2}\right) & \rightarrow \mathfrak{n} / \mathfrak{n}^{2} & \rightarrow t_{B}^{*} & \rightarrow 0
\end{array}
$$

We have that, since $\mathfrak{m}$ is maximal in $A, \mu A \subseteq \mathfrak{m}$ and the elements that go in $\mathfrak{m}^{2}$ are those of $\mu A \cap \mathfrak{m}^{2}$, so the map on the left is injective; moreover we notice that $\mathfrak{m} / \mathfrak{m}^{2} / \mu A /\left(\mathfrak{m}^{2} \cap \mu A\right)$ is isomorphic to $\mathfrak{m} /\left(\mathfrak{m}^{2}+\mu A\right)$, which is $t_{A}^{*}$ (so the map on the right is surjective). So we have shown that the rows of the diagram are exact.

Thus, in the diagram, $\alpha$ is surjective for all morphisms $B \rightarrow A$ in $\hat{\mathbf{C}}$ because $B \rightarrow A$ is a morphism of $\Lambda$-algebras and the following diagram commutes:

$(\Leftarrow)$ It follows that, if $\gamma$ is surjective, $\beta$ is surjective as well. But the induced map $\operatorname{gr}(B) \rightarrow$ $\operatorname{gr}(A)$ on the graded rings is a surjection (in general a basis of $\mathfrak{m} / \mathfrak{m}^{2}$ as vectorial $k$ space is a system of generators of $\operatorname{gr}(A)$ as $k$-algebra).
Now, using [1] (§2, No. 8, Theorem 1), since $B$ is complete, $A$ is separated $\left(\cap \mathfrak{m}^{i}=0\right)$ and $\cup \mathfrak{m}^{i}=A$, we can conclude that $B \rightarrow A$ is surjective.
$(\Rightarrow)$ Conversely, suppose that $f: B \rightarrow A$ is surjective. In this case we get $f(\mathfrak{n})=\mathfrak{m}$, i.e. we have that $\forall x \in \mathfrak{m} \quad \exists y \in B$ such that $f(y)=x$. In fact if $x \in \mathfrak{m}$ then $\exists y \in B$ such that
$f(y)=x$. If $y \notin \mathfrak{n}$, then $y$ is a unit and so it's $x$ since $f$ is morphism of rings, but this is a contradiction. Notice that the condition $f(\mathfrak{n})=\mathfrak{m}$ is stronger than $f^{-1}(\mathfrak{m})=\mathfrak{n}$, the one for local morphisms (for example, we can consider the function $f: \mathbb{Z}_{p} \rightarrow \mathbb{Z}_{p}[[x]]$ ). In this case $f^{-1}(\mathfrak{m})=\mathfrak{n}=\mathbb{Z}_{p} \cap \mathfrak{m}=p \mathbb{Z}_{p}=n$ but $f(\mathfrak{n})=f\left(p \mathbb{Z}_{p}\right)=p \mathbb{Z}_{p} \neq(x, p)$. Since $f(\mathfrak{n})=\mathfrak{m}, t_{B}^{*}=\mathfrak{n} /\left(\mathfrak{n}^{2}+\mu B\right)$ and $t_{A}^{*}=\mathfrak{m} /\left(\mathfrak{m}^{2}+\mu A\right)$, it follows that $t_{B}^{*} \rightarrow t_{A}^{*}$ is surjective.

Let $p: B \rightarrow A$ be a surjection in $\mathbf{C}$.

Definition 3.1. We say that $p$ is a small extension if the kernel of $p$ is a nonzero principal ideal $(t)$ such that $\mathfrak{m} \cdot t=(0)$, where $\mathfrak{m}$ is the maximal ideal of $B$.

Definition 3.2. We say that $p$ is essential if for any morphism $q: C \rightarrow B$ in $\mathbf{C}$ such that $p q$ is surjective, it follows that $q$ is surjective.

From lemma 3.1 we obtain:

Lemma 3.2. Let $p: B \rightarrow A$ be a surjection in $\boldsymbol{C}$. Then:
(i) $p$ is essential if and only if the induced map $p_{*}: t_{B}^{*} \rightarrow t_{A}^{*}$ is an isomorphism.
(ii) If $p$ is a small extension, then $p$ is not essential if and only if $p$ has a section $s: A \rightarrow B$, with $p s=1_{A}$.

Proof. (i) Let $p_{*}$ be an isomorphism, $q: C \rightarrow B$ morphism. Then we have:

$$
t_{C}^{*} \xrightarrow{q_{*}} t_{B}^{*} \xrightarrow{p_{*}} t_{A}^{*}
$$

Since $p q$ is surjective, by lemma 3.1 we get that $(p q)_{*}=p_{*} q_{*}$ is surjective, and so $p_{*}$ is surjective. Now, applying lemma 3.1 again, we get that $q$ is surjective, and so $p$ is essential.
Conversely, let $\tilde{t_{1}}, \ldots, \tilde{t_{r}}$ be a basis for $t_{A}^{*}=\mathfrak{m}_{A} /\left(\mathfrak{m}_{A}^{2}+\mu A\right)$, and let $t_{1}, \ldots, t_{r}$ preimages
in $B$ (they are in the maximal ideal of $B$ ).
Let's now define $C:=\Lambda\left[t_{1}, \ldots, t_{r}\right]$ as the $\Lambda$-algebra generated by the elements $t_{1}, \ldots, t_{r}$.
We have that $C \subseteq B$. Moreover if we consider the restriction of $p$ over $C$, we obtain a surjective map of $\Lambda$-algebras. Then we have that $p$ is essential, so the map from $C$ to $B$ is surjective and $C=B$.

Since $C:=\Lambda\left[t_{1}, \ldots, t_{r}\right]$ we get that $\mathfrak{m}_{C} /\left(\mathfrak{m}_{C}^{2}+\mu C\right)$ is generated by at most $r$ elements, so $\operatorname{dim}_{K} t_{C}^{*} \leq r$.

Then we get:

$$
\operatorname{dim}_{K} t_{B}^{*}=\operatorname{dim}_{K} t_{C}^{*} \leq r=\operatorname{dim}_{K} t_{A}^{*}
$$

Moroever, since we have a surjection from $B$ to $A$, we get that the map $t_{B}^{*} \rightarrow t_{A}^{*}$ is also surjective, so $\operatorname{dim}_{K} t_{B}^{*} \geq \operatorname{dim}_{K} t_{A}^{*}$. We can now conclude that $\operatorname{dim}_{K} t_{B}^{*}=\operatorname{dim}_{K} t_{A}^{*}$, and so $t_{B}^{*} \simeq t_{A}^{*}$.
(ii) Let's first suppose that $p$ has a section $s$. In particular $s$ can't be surjective, otherwise $p$ would be injective and it is not possible since $p$ is small. Then $p s=1_{A}$ is surjective, so $p$ is not essential.

Conversely, if $p$ is not essential, then $C$ is properly contained in $B$ because $p$ restricted at $C$ is essential (it follows by $(i)$ and by construction of $C$ ). Since by hypotesis we have that $m(t)=0$, so $t^{2}=0$ and length $(t)=1$, so we get:

$$
\operatorname{length}(B)=\operatorname{length}(A)+\operatorname{length}(t)=\text { length }(A)+1
$$

Then, since the restriction of $p$ at $C$ is surjective,

$$
\operatorname{length}(C) \geq \operatorname{length}(A)
$$

and

$$
\operatorname{length}(C)<\operatorname{length}(B)=\operatorname{length}(A)+1
$$

i.e. length $(C) \leq$ length $(A)$.

We get that length $(C)=\operatorname{length}(A)$ and, from the surjectivity of $p$ restricted to $C$, we can conclude that $C \simeq A$. In particular, since the isomorphism from $A$ to $C$ is a section of $p$, we can conclude.

We shall consider only covariant functors $F$ from $\mathbf{C}$ to Sets, such that $F(k)$ contains just one element.

Definition 3.3. By a couple for $F$ we mean a pair $(A, \xi)$ where $A \in \mathbf{C}$ and $\xi \in F(A)$. A morphism of couples $u:(A, \xi) \rightarrow\left(A^{\prime}, \xi^{\prime}\right)$ is a morphism $u: A \rightarrow A^{\prime}$ in $\mathbf{C}$ such that $F(u)(\xi)=\xi^{\prime}$. If we extend $F$ to $\hat{\mathbf{C}}$ by the formula $\hat{F}(A)=\lim F\left(A / \mathfrak{m}^{n}\right)$ we may speak analogously of pro-couples and morphisms of pro-couples.

For any ring $R$ in $\hat{\mathbf{C}}$, we set $h_{R}(A)=\operatorname{Hom}(R, A)$ to define a functor $h_{R}$ on $\mathbf{C}$. Now, if $F$ is any functor on $\mathbf{C}$, and $R$ is in $\hat{\mathbf{C}}$, we have a canonical isomorphism:

$$
\hat{F}(R) \xrightarrow{\sim} \operatorname{Hom}\left(h_{R}, F\right)
$$

To each element of $\hat{F}(R)$ we can in fact associate a morphism of functors $h_{R} \rightarrow F$.
Let $\xi=\lim _{\longleftarrow} \xi_{n}$ element in $\hat{F}(R)$. Then each $u: R \rightarrow A$ factors through $u_{n}: R / \mathfrak{m}^{n} \rightarrow A$ for some $n$ because $\operatorname{ker}(u) \supseteq \mathfrak{m}^{n}$. This is not true in general but it works in this case because $A$ is Artinian, so $\mathfrak{m}_{A}^{k}=0$ for some $k$ and this implies that $u\left(\mathfrak{m}^{k}\right) \subseteq \mathfrak{m}_{A}^{k}$. So we can assign to $u \in h_{R}(A)$ the element $F\left(u_{n}\right)\left(\xi_{n}\right)$ of $F(A)$.
Viceversa, we can associate to $h_{R} \rightarrow F$ an element of $\hat{F}(R)$. We can in fact consider for each $n$ the map:

$$
h_{R}\left(R / \mathfrak{m}^{n}\right) \rightarrow F\left(R / \mathfrak{m}^{n}\right)
$$

where an element in the domain is given by the canonical projection $\Pi$. The images form an inverse system by construction.

This means that we can associate to $h_{R} \rightarrow F$ the inverse limit of those elements.

Definition 3.4. We say that a pro-couple $(R, \xi)$ for $F$ pro-represents $F$ if the morphism $h_{R} \rightarrow F$ induced by $\xi$ is an isomorphism.

Unfortunately, many interesting functors are not pro-representable: an attempt of looking for some kind of "universal object" is given by the definition below.

Definition 3.5. A morphism $F \rightarrow G$ of functors is smooth if for any surjection $B \rightarrow A$ in C, the morphism:

$$
F(B) \rightarrow F(A) \times_{G(A)} G(B)
$$

obtained by the following contruction

is surjective.
Remark 3.2. It is enough to check surjectivity in the equation 3.5 for small extensions $B \rightarrow A$.

In fact the idea is that every surjective morphism $f: B \rightarrow A$ factor through a small extension. In fact $B$ is Noetherian and $\operatorname{ker}(f)=\left(x_{1}, \ldots, x_{n}\right)$ is finitely generated, so we get that $\operatorname{ker}(f) \supseteq\left(x_{2}, \ldots, x_{n}\right)+\mathfrak{m}\left(x_{1}\right)$, so $f$ factors through:

and the map $B /\left(x_{2}, \ldots x_{n}\right)+\mathfrak{m}\left(x_{1}\right) \rightarrow A$ is a small extension (in fact its kernel goes to zero if multiplied by the maximal ideal).

So, if we use induction on the length, we prove the remark.
Remark 3.3. If $F \rightarrow G$ is smooth, then $\hat{F} \rightarrow \hat{G}$ is surjective, in the sense that $\hat{F}(A) \rightarrow \hat{G}(A)$ is surjective fo all $A$ in $\hat{C}$. Since $\hat{F}(A)=\underset{\rightleftarrows}{\lim } F\left(A / \mathfrak{m}^{n}\right)$, we prove the remark working by
induction on each level.
If $n=1$, then our function is surjective because we have just one element in the domain and one in the codomain.

Now, we have the function $A / \mathfrak{m}^{n+1} \rightarrow A / \mathfrak{m}^{n}$, and we want to show that, given that the function $F\left(A / \mathfrak{m}^{n}\right) \rightarrow G\left(A / \mathfrak{m}^{n}\right)$ is surjective, also $F\left(A / \mathfrak{m}^{n+1}\right) \rightarrow G\left(A / \mathfrak{m}^{n+1}\right)$ is surjective. From the fact that $F \rightarrow G$ is smooth, it follows the surjectivity of the function

$$
F\left(A / \mathfrak{m}^{n+1}\right) \rightarrow F\left(A / \mathfrak{m}^{n}\right) \times_{G\left(A / \mathfrak{m}^{n}\right)} G\left(A / \mathfrak{m}^{n+1}\right)
$$

But now we have that the function:

$$
F\left(A / \mathfrak{m}^{n}\right) \times_{G\left(A / \mathfrak{m}^{n}\right)} G\left(A / \mathfrak{m}^{n+1}\right) \rightarrow G\left(A / \mathfrak{m}^{n+1}\right)
$$

is surjective, so our statement follows by composition.

Proposition 3.3. (i) Let $R \rightarrow S$ be a morphism in $\hat{C}$. Then $h_{S} \rightarrow h_{R}$ is smooth if and only if $S$ is a power series ring over $R$.
(ii) If $F \rightarrow G$ and $G \rightarrow H$ are smooth morphisms of functors, then the composition $F \rightarrow H$ is smooth.
(iii) If $u: F \rightarrow G$ and $v: G \rightarrow H$ are morphisms of functors, then the composition $F \rightarrow H$ is smooth
(iv) If $F \rightarrow G$ and $H \rightarrow G$ are morphisms of functors such that $F \rightarrow G$ is smooth, then $F \times_{G} H \rightarrow H$ is smooth.

Proof. (i) ( $\Rightarrow$ ) Suppose $h_{S} \rightarrow h_{R}$ is smooth. Let $\mathfrak{r}$ (resp $\mathfrak{s}$ ) be the maximal ideal in $R$ (resp S), and pick $x_{1}, \ldots x_{n}$ in $S$ such that $\bar{x}_{1}, \ldots, \bar{x}_{n}$ is a basis for $t_{S / R}^{*}=\mathfrak{s} /\left(\mathfrak{s}^{2}+\mathfrak{r} S\right)$ (relative cotangent space).
Set $T=R\left[\left[X_{1}, \ldots X_{n}\right]\right]$ and denote the maximal ideal of $T$ by $\mathfrak{t}$. We want to show that $T \cong S$.

First we notice that $T$ is Noetherian and local because $R$ has those properties, and $T$ is complete with respect to the $\mathfrak{t}$-adic topology by the definition of the power series ring.

We have that $x_{1}, \ldots, x_{n}$ generate $S$ as an $R$-module: in fact we have that the $\bar{x}_{1}, \ldots, \bar{x}_{n}$ generate $S /\left(\mathfrak{s}^{2}+\mathfrak{r} S\right)$ as $R / \mathfrak{r}$-vector space. So $S$ is generated by $x_{1}, \ldots x_{n}$ as $R$-module.

It follows that in order to define a morphism of $R$-modules on $S$ it is enough to define the images of $x_{1}, \ldots x_{n}$. We can define a morpshim of $R$-algebras $u_{1}: S \rightarrow$ $T /\left(\mathfrak{t}^{2}+\mathfrak{r} T\right)$ obtained by mapping $x_{1}$ on the residue class of $X_{i}$. We notice that $u_{1}$ as it is induced by the following commutative diagram:

Now, since $h_{S} \rightarrow h_{R}$ is smooth, by considering the $R$-algebras surjective morphism $T / \mathfrak{t}^{2} \rightarrow T /\left(\mathfrak{t}^{2}+\mathfrak{r} T\right)$, we get the surjectivity of:

$$
h_{S}\left(T / \mathfrak{t}^{2}\right) \rightarrow h_{S}\left(T /\left(\mathfrak{t}^{2}+\mathfrak{r} T\right)\right) \times_{h_{R}\left(T /\left(\mathfrak{t}^{2}+\mathfrak{r} T\right)\right.} h_{R}\left(T / \mathfrak{t}^{2}\right)
$$

We note that:

$$
h_{S}\left(T /\left(\mathfrak{t}^{2}+\mathfrak{r} T\right)\right) \subseteq h_{S}\left(T /\left(\mathfrak{t}^{2}+\mathfrak{r} T\right)\right) \times_{h_{R}\left(T /\left(\mathfrak{t}^{2}+\mathfrak{r} T\right)\right.} h_{R}\left(T / \mathfrak{t}^{2}\right)
$$

because $R$ is projective as an $R$-module (it is a module over itself).
By smoothness $u_{1}$ lifts to $u_{2}: S \rightarrow T / \mathfrak{t}^{2}$.
Applying the same idea again we can lift to $u_{3}: S \rightarrow T /\left(\mathfrak{t}^{3}, u_{4}, \ldots\right)$ etc. Since $T$ is complete, we get $u: S \rightarrow T$ which induces an isomorphism of $t_{S / R}^{*}$ with $t_{T / R}^{*}$ (by choice of $u_{1}$ ) so that $u$ is a surjection by lemma 3.1. Furthermore, if we choose $y_{i} \in S$ such that $u y_{i}=X_{t}$, we can set $v X_{i}=y_{i}$ and produce a local morphism
$v: T \rightarrow S$ of algebras such that $u v=1_{T}$; in particular $v$ is an injection.
Clearly $v$ induces a bijection on the cotangent spaces, so $v$ is also a surjection (see lemma 3.1). Hence $v$ is an isomorphism of $T=R\left[\left[X_{1}, \ldots X_{n}\right]\right]$ with $S$.
$(\Leftarrow)$ Conversely, let $S=R\left[\left[X_{1}, \ldots, X_{n}\right]\right]$, then it follows the smoothness of the function $h_{R\left[\left[X_{1}, \ldots, X_{n}\right]\right]} \rightarrow h_{R}$.
In fact, if we consider the function $s: B \rightarrow A$, then the map:

$$
h_{R\left[\left[X_{1}, \ldots, X_{n}\right]\right]}(B) \rightarrow h_{R\left[\left[X_{1}, \ldots, X_{n}\right]\right]}(A) \times_{h_{R}(A)} h_{R}(B)
$$

is surjective.
In particular, to $(g, f) \in h_{R\left[\left[X_{1}, \ldots, X_{n}\right]\right]}(A) \times_{h_{R}(A)} h_{R}(B)$ we associate the element of $h_{R\left[\left[X_{1}, \ldots, X_{n}\right]\right]}(B)$ given by :

$$
\begin{aligned}
R \ni r & \mapsto f(r) \\
X_{i} & \mapsto s^{-1}\left(g\left(X_{i}\right)\right)
\end{aligned}
$$

with $\left.g\right|_{R}=s \circ f$ acording to the following diagram:

The proof of $(i),(i i i),(i v)$ is formal and similar to the first one.

Remark 3.4. Let $k[\epsilon]$, where $\epsilon^{2}=0$, denote the ring of dual numbers over $k$. For any functor $F$, the set $F(k[\epsilon])$ is called the tangent space to $F$, and it is denoted by $t_{F}$.

In particular, if $F=h_{R}$, then it exists a canonical isomorphism $t_{F} \cong t_{R}$ :

$$
\operatorname{Hom}_{k}\left(t_{R}^{*}, k\right)=t_{R} \cong t_{h_{R}}=h_{R}(k[\epsilon])=\operatorname{Hom}_{\Lambda}(R, k[\epsilon])
$$

In fact, if we consider $g \in \operatorname{Hom}_{\Lambda}(R, k[\epsilon])$, we can associate the morphism which sends $[t] \in \mathfrak{m}_{R} /\left(\mathfrak{m}_{R}^{2}+\mu R\right)$ to the coefficient of $\epsilon$ in $g(t)(t$ representative in $[t])$. In particular, this is a morphism of $k$-vector spaces from $t^{*}$ to $k$, in fact:

$$
\begin{array}{r}
k_{1}[t]=\left[\lambda_{1} t\right] \mapsto \text { coef. of } \epsilon \text { in } g\left(\lambda_{1} t\right)=\bar{\lambda}_{1} g(t)_{\epsilon}=k_{1} g(t)_{\epsilon} \\
{\left[t_{1}\right]+\left[t_{2}\right] \mapsto \text { coef. of } \epsilon \text { in } g\left(t_{1}+t_{2}\right)=g\left(t_{1}\right)_{\epsilon}+g\left(t_{2}\right)_{\epsilon}}
\end{array}
$$

where in both cases we used the fact that $g \in \operatorname{Hom}_{\Lambda}(R, k[\epsilon])$.
Conversely, given $f \in \operatorname{Hom}_{k}\left(t_{R}^{*}, k\right)$, we consider the diagram:

For $\bar{t} \in \mathfrak{m}_{R} /\left(\mathfrak{m}_{R}^{2}+\mu R\right)$.
We can define the map from $R$ to $k[\epsilon]$ as the composition of the maps above and we get a $\Lambda$-module morphism. Usually $t_{F}$ will have an intrinsic vector space structure.

Definition 3.6. A pro-couple $(R, \xi)$ for a functor $F$ is called a pro-representable hull of $F$, or just a hull of $F$, if the induced map $h_{R} \rightarrow F$ is smooth, and if the induced map $t_{R} \rightarrow t_{F}$ of tangent spaces is a bijection.

Remark 3.5. If $(R, \xi)$ pro-represents $F$, then $(R, \xi)$ is a hull of $F$. In fact, from the fact that $h_{R} \rightarrow F$ is an isomorphism it follows that $h_{R} \rightarrow F$ is smooth ( $B \rightarrow A$ is surjective, so $h_{R}(B) \rightarrow h_{R}(A) \times_{F(A)} F(B)$ is surjective , so $t_{F}=F(k[\epsilon]) \cong h_{R}(k[\epsilon]) \cong t_{R}$.

If $(R, \xi)$ pro-represents $F$, then $(R, \xi)$ is unique up to canonical isomprhism (while if it is hull it is unique uo to non canonical isomorphisms).

Remark 3.6. If $f: R \rightarrow R$ is a surjective endomorphism and $R$ is Noetherian, then $f$ is injective.

We can easily prove this statement using tools from commutative algebra.
If we consider the chain:

$$
\operatorname{ker}(f) \subseteq \operatorname{ker}\left(f^{2}\right) \subseteq \ldots
$$

since $R$ is Noetherian we must have $\operatorname{ker}\left(f^{n}\right)=\operatorname{ker}\left(f^{n+1}\right)=\ldots$ for some $n$.
Now we claim that $\operatorname{ker}\left(f^{n}\right) \cap \operatorname{Im}\left(f^{n}\right)=0$. We just have to show one inclusion.
Let $x \in \operatorname{ker}(f) \cap \operatorname{Im}\left(f^{n}\right)$, then $f^{n}(x)=0$ and there exists $y \in M$ such that $x=f^{n}(y)$. So, by substitution, we get that $f^{2 n}(y)=0$, which means that $y \in \operatorname{ker}\left(f^{2 n}\right)=\operatorname{ker}\left(f^{n}\right)$, hence $f^{n}(y)=0$. This implies that $x=0$, so our claim follows.
Now, since $f$ is surjective, it follows that $\operatorname{Im}\left(f^{n}\right)=M$. However, we have that $\operatorname{ker}\left(f^{n}\right) \subset M$, so that $0=\operatorname{ker}(f) \cap M=\operatorname{ker}(f)$, so $F$ is injective and hence an isomorphism.

Proposition 3.4. Let $(R, \xi)$ and $\left(R^{\prime}, \xi^{\prime}\right)$ be hulls of $F$. Then there exists an isomorphim $u: R \rightarrow R^{\prime}$ such that $F(u)(\xi)=\xi^{\prime}$.

Proof. If $(R, \xi)$ is hull, then the morphism $h_{R} \rightarrow F$ inudeced by $\xi$ is smooth and so it is surjective. It follows that in particular $h_{R}\left(R^{\prime}\right) \rightarrow F\left(R^{\prime}\right)$ is surjective, so, since $\xi \in F\left(R^{\prime}\right)$, $\exists u \in h_{R}\left(R^{\prime}\right)$ such that $F\left(u_{n}\right)\left(\xi_{n}\right)=\xi_{n}^{\prime}$. So, applying the previous theorem, we get a morphisms of couple $u:(R, \xi) \rightarrow\left(R^{\prime}, \xi^{\prime}\right)$. Moreover, since $(R, \xi)$ is a hull, we have a bijection $t_{R} \cong t_{F}$.

In the same way, if we consider the pair $\left(R^{\prime}, \xi^{\prime}\right)$, we get that exists a morphism of couple $u^{\prime}:\left(R^{\prime}, \xi^{\prime}\right) \rightarrow(R, \xi)$ and $t_{R}^{\prime} \cong t_{F}$ is a bijection. So we get that $t_{R} \cong t_{F} \cong t_{R}^{\prime}$, so $t_{R} \cong t_{R}^{\prime}$. It follows that $u^{\prime} u$ induces an isomorphism on $t_{R}^{*}$ so that $u^{\prime} u$ is a endomorphism of $R$ by lemma 3.1. But by the remark 3.6 we know that a surjective endomorphism of any Noetherian ring is an isomorphism and we can conclude.

Remark 3.7. Let $(R, \xi)$ be a hull of $F$. Then $R$ is a power series ring over $\Lambda$ if and only if $F$ maps surjections $B \rightarrow A$ in $\mathbf{C}$ into surjections $F(B) \rightarrow F(A)$. In fact the state condiction on $F$ is equivalent to the smoothness of the natural morphism $F \rightarrow h_{\Lambda}$. By applying the
proposition 3.3 (ii) and (iii) to the diagram:

we can conclude that $h_{R} \rightarrow h_{\Lambda}$ is smooth if and only if $F \rightarrow h_{\Lambda}$ is.
Now, using proposition 3.3 (i) we can can conclude that $R$ is a power series ring over $\Lambda$.

Lemma 3.5. Suppose $F$ is a functor such that

$$
F\left(k[V] \times_{k} k[W]\right) \xrightarrow{\sim} F(k[V]) \times F(k[W])
$$

for vector spaces $V$ and $W$ over $k$, where $k[V]$ denotes the ring $k \oplus V$ of $C$ in which $V$ is a square zero ideal. Then $F(k[V])$, and in particular $t_{F}=F([k[\epsilon])$, has a canonical vector space structure, such that $F(k[V]) \cong t_{F} \otimes V$.

Proof. We prove our statement in the particular case: $k[V]=k[W]=k[\epsilon]$.
In this case we have, by hypothesis:

$$
b: F\left(k[\epsilon] \times_{k} k[\epsilon]\right) \xrightarrow{\sim} F(k[\epsilon]) \times F(k[\epsilon])
$$

We get the following results.

- Sum:

where:

$$
\begin{aligned}
F^{+}: k[\epsilon] \times{ }_{k} k[\epsilon] & \rightarrow k[\epsilon] \\
(a+b \epsilon, a+c \epsilon) & \mapsto a+(b+c) \epsilon
\end{aligned}
$$

- Scalar multiplication:

where:

$$
\begin{aligned}
F_{m \lambda}: k[\epsilon] & \rightarrow k[\epsilon] \\
a+b \epsilon & \mapsto a+\lambda b \epsilon
\end{aligned}
$$

### 3.2 The Main Theorem

### 3.2.1 Statement

Theorem 3.6. Let $F$ be a functor from $\boldsymbol{C}$ to Sets such that $F(k)=(e)$ (=one point). Let $A^{\prime} \rightarrow A$ and $A^{\prime \prime} \rightarrow A$ be morphisms in $C$, and consider the map

$$
\begin{equation*}
F\left(A^{\prime} \times_{A} A^{\prime \prime}\right) \rightarrow F\left(A^{\prime}\right) \times_{F(A)} F\left(A^{\prime \prime}\right) \tag{3.1}
\end{equation*}
$$

Then:
(1) $F$ has a hull if and only if $F$ has properties $\left(H_{1}\right),\left(H_{2}\right),\left(H_{3}\right)$ below:
$\left(H_{1}\right) 3.1$ is a surjection whenever $A^{\prime \prime} \rightarrow A$ is a small extension.
$\left(H_{2}\right) 3.1$ is a bijection when $A=k, A^{\prime \prime}=k[\epsilon]$.
$\left(H_{3}\right) \operatorname{dim}_{k}\left(t_{F}\right)<\infty$
(2) $F$ is pro-representable if and only if, for any small extension $A^{\prime} \rightarrow A, F$ has the additional property $\left(H_{4}\right)$ :

$$
\left(H_{4}\right) F\left(A^{\prime} \times_{A} A^{\prime}\right) \xrightarrow{\sim} F\left(A^{\prime}\right) \times_{F(A)} F\left(A^{\prime}\right)
$$

### 3.2.2 Preliminary results

Remark 3.8. First we notice that if $F \cong h_{R}$, then 3.1 is an isomorphism for all $A^{\prime} \rightarrow A$ and $A^{\prime \prime} \rightarrow A$ morphisms, i.e. the three conditions are necessary for the pro-representability. In fact we have the maps:

$$
\begin{aligned}
\phi: h_{R}\left(A^{\prime} \times_{A} A^{\prime \prime}\right) & \rightarrow h_{R}\left(A^{\prime}\right) \times_{h_{R}(A)} h_{R}\left(A^{2}\right) \\
f & \mapsto \quad\left(g^{\prime}, g^{\prime \prime}\right) \\
t(r)=(v(r), w(r)) & \leftrightarrow \quad(v, w)
\end{aligned}
$$

where $g^{\prime}(r)=\Pi_{1} \circ f(r)$ and $g^{\prime \prime}(r)=\Pi_{2} \circ f(r)$, for the projections $\Pi_{1}, \Pi_{2}$.
In particular we get that if $F$ is pro-representable, then the four conditions hold.

Remark 3.9. The condition $\left(H_{2}\right)$ implies that $t_{F}$ is a vector space by lemma 3.5.
We want to prove that from $\left(H_{2}\right)$ follows that the function:

$$
F\left(A^{\prime} \times k[W]\right) \rightarrow F\left(A^{\prime}\right) \times F(k[W])
$$

is an isomorphism $\forall A^{\prime}, \forall W$. In order to do that we proceed by induction on the dimension of $W$.

If $\operatorname{dim} W=1$, then $k[W]=k[\epsilon]$ and $F\left(A^{\prime} \times k[W]\right) \rightarrow F\left(A^{\prime}\right) \times F(k[W])$ is a bijection by $H_{2}$. Let now $\operatorname{dim} W=n+1$, then we can rewrite $k[W] \cong k\left[W^{\prime}\right] \times_{k} k[\epsilon]$ where $\operatorname{dim} W^{\prime}=n$. We get that:

$$
\begin{aligned}
F\left(A^{\prime} \times_{k} k[W]\right) & \cong F\left(\left(A^{\prime} \times_{k} k\left[W^{\prime}\right]\right) \times_{k} k[\epsilon]\right) \\
& \cong F\left(A^{\prime} \times_{k} k\left[W^{\prime}\right]\right) \times F(k[\epsilon]) \\
& \cong F\left(A^{\prime}\right) \times F\left(k\left[W^{\prime}\right]\right) \times F(k[\epsilon]) \\
& \cong F\left(A^{\prime}\right) \times F\left(k\left[W^{\prime}\right] \times_{k} k[\epsilon]\right)
\end{aligned}
$$

Where we have used $\left(H_{2}\right)$ in the first and third passage and the inductive hypotesis in the second one.

Remark 3.10. By induction on length $\left(A^{\prime \prime}\right)$ - length $(A)$ it follows from $\left(H_{1}\right)$ that 3.1 is surjective $\forall A^{\prime \prime} \rightarrow A$ surjection.

Remark 3.11. We can view condition $\left(H_{4}\right)$ in the following way. For each $A$ in $\mathbf{C}$ and each ideal $I$ in $A$ such that $\mathfrak{m}_{A} I=(0)$, we have a ring isomorphism:

$$
A \times_{A / I} A \xrightarrow{\sim} A \times_{k} k[I]
$$

induced by the map:

$$
(x, y) \mapsto\left(x, x_{0}+y-x\right)
$$

where $x$ and $y$ are in $A$ and $x_{0}$ is in the $k$ residue of $x$. It is in fact easy to check that the map is:

- injective: $\left(x, x_{0}+y-x\right)=(0,0) \quad \Rightarrow \quad x=0$ and $y=0$
- surjective: one element of $A \times_{k} k[I]$ is of the form $(a, k+x)$, with $x \in I: x^{2} \cong 0$. It follows that $\bar{a}=k$, i.e. we have elements of the type $(a, \bar{a}+x)$ with $x \in I, x^{2} \cong 0$. So the element $(a, \bar{a}+x)$ is the image of $(a, x+a)$.
- respect the additive structure: $\left(x_{1}+x_{2}, y_{1}+y_{2}\right) \mapsto\left(x_{1}+x_{2}, \overline{x_{1}+x_{2}}+y_{1}+y_{2}-x_{1}-x_{2}\right)$ which is equal to $\left(x_{1}, \overline{x_{1}}+y_{1}-x_{1}\right)+\left(x_{2}, \overline{x_{2}}+y_{2}-x_{2}\right)$

Now, given a small extension $p: A^{\prime} \rightarrow A$ with kernel $I$ we get, by $\left(H_{2}\right)$ and the isomorpshim above, the map:

$$
F\left(A^{\prime}\right) \times\left(t_{F} \otimes I\right) \rightarrow F\left(A^{\prime}\right) \times_{F(A)} F\left(A^{\prime}\right)
$$

In fact we get:

$$
A^{\prime} \times_{A^{\prime} / I} A^{\prime} \cong A^{\prime} \times_{k} k[I] \quad \Rightarrow \quad F\left(A^{\prime} \times_{A^{\prime} / I} A^{\prime}\right) \cong F\left(A^{\prime} \times_{k} k[I]\right)
$$

so, by applying $\left(H_{2}\right)$, we have that:

$$
F\left(A^{\prime} \times_{A^{\prime} / I} k[I]\right) \quad \text { is in bijection with } F\left(A^{\prime} \times A_{A^{\prime} / I} A^{\prime}\right), \quad \text { and } \quad A^{\prime} / I \cong A .
$$

Now we can consider the diagram:

which is easily seen to determine, $\forall \eta \in F(A)$, a group action of $t_{F} \otimes I$ on the subset $F(p)^{-1}(\eta)$ of $F\left(A^{\prime}\right)$. Moreover, $\left(H_{2}\right)$ implies that this action is transitive, while $\left(H_{4}\right)$ is precisely the condition that this action makes $F(p)^{-1}(\eta)$ a principal homogeneous space under $t_{F} \otimes I$.

### 3.2.3 Proof of the Theorem

We can finally prove the Schlessinger Criterion.

Proof. $\quad(1)(\Leftarrow)$ We first suppose that $F$ satisfies the conditions $\left(H_{1}\right),\left(H_{2}\right),\left(H_{3}\right)$.
Let $t_{1}, \ldots, t_{r}$ a basis for the dual of $t_{F}$ and let $S=\Lambda\left[\left[T_{1}, \ldots, T_{r}\right]\right]$, with $\mathfrak{n}$ maximal ideal of $S$. We will construct $R$ as the projective limit of successive quotients of $S$.

Let:

$$
R_{2}=\frac{S}{\mathfrak{n}^{2}+\mu S} \cong k[\epsilon] \times_{k} \cdots \times_{k} k[\epsilon]=k\left[t_{F}^{*}\right]
$$

In fact we have that $t_{S}^{*}$ can be identified with $t_{F}^{*}$ because they are vector spaces of the same dimension. In particular, we have:

$$
F\left(R_{2}\right) \cong F\left(k\left[t_{F}^{*}\right] \stackrel{\left(H_{2}\right)}{\cong} t_{F} \otimes t_{F}^{*}\right.
$$

and since $\sum t_{i}^{v} \otimes t_{i} \in t_{F} \otimes t_{F}^{*}$ we can choose $\xi_{2}=\sum t_{i}^{v} \otimes t_{i}$ and using a similar construction as in 3.4, we know that it induces a map from $h_{R_{2}}$ to $F$.

Now, since $t_{F}^{*} \cong t_{S}^{*} \cong t_{R_{2}}^{*}$, we get that $\xi_{2}$ induces a bijection between $t_{R_{2}}$ and $t_{F}$ (dual of the isomorphism used to identify the $t_{i}$ as basis for the space $t_{F}^{*}$ ).

We can now work by induction. Suppose we have found $\left(R_{q}, \xi_{q}\right)$, with $R_{q}=S / J_{q}$. We are looking for an ideal $J_{q+1}$ in $S$, minimal among those ideals $J$ in $S$ satisfying the following conditions:
(a) $\mathfrak{n} J_{q} \subseteq J \subseteq J_{q}$
(b) $\xi_{q}$ lifts to $S / J$

We want to show that the collection of those ideals is non-empty and closed under intersection. Since $J_{q}$ satisfies the conditions, the collection is non empty. Moreover, the first condition is obviously closed under arbitrary intersections, so we just need to check the second one.

We first notice that the ideals $J$ correspond to subspaces of the finite dimensional vector space $J_{q} / \mathfrak{n} J_{q}$. This follows from the fact that we have a Noetherian ring and we are considering an $S$-module. In fact, we remark that in general, if $S \supseteq M$, for an $S$-module $M$ such that $\mathfrak{n} M=0$, then $M$ is an $S / \mathfrak{n}=k$-module.

It follows that it suffices to check the condition for finite (so pairwise) intersection. Let's now $J, K$ be ideals that satisfy these conditions. Since we are in $J_{q} / \mathfrak{n} J_{q}$, we may enlarge $J$ so that $J+K=J_{q}$, without changing the intersection $J \cap K$. Then:

$$
S / J \times_{S / J_{q}} S / K \cong S /(J \cap K)
$$

In fact we have the following commutative diagram:

where

$$
Z=S / J \times_{S /(J+K)} S / K
$$

and exists because of the property of the pull-back.
Now, using $H_{1}$ and the remark 3.10, we get that we can lift $\xi_{q}$ at $S / J \cap K$, so $J \cap K=J_{q} \cap K$ satisfies our condition.

Thus we can choose $J_{q}$ to be the intersection of all the elements of the collection considered above, and we get:

$$
R_{q+1}=S / J_{q+1}
$$

and

$$
\xi_{q+1} \in F\left(R_{q+1}\right)
$$

where $\xi_{q+1}$ can be arbitrarily chosen as long as it projects onto $\xi_{q} \in F\left(R_{q}\right)$.
Now let $J=\cap J_{q}$ for $q=2,3, \ldots$, we have $R=S / J$.
We have that $\mathfrak{n}^{q} \subseteq J_{q}$, and, in fact:

$$
J_{q} \supseteq \mathfrak{n} J_{q-1} \supseteq \mathfrak{n}\left(\mathfrak{n} J_{q-2}\right) \supseteq \cdots \supseteq \mathfrak{n}^{q-3} \mathfrak{n} J_{2}
$$

and $J_{2} \supseteq \mathfrak{n}^{2}$, which proves our statement. Since this is true, we have that the $J_{q} / J$ form a basis for the topology in $R$, so that $R=\lim \xi_{q}$.
Now, due to the choice made for $R_{2}$, we get that $t_{F} \cong t_{R}$, so we just need to check that $h_{R} \rightarrow F$ is smooth.

Let $p:\left(A^{\prime}, \eta^{\prime}\right) \rightarrow(A, \eta)$ a morphism of couples, where $p$ is a small extension, $A=A^{\prime} / I$ and $u:(R, \xi) \rightarrow(A, \eta)$ is a given morphism. We first notice that we can restrict our analysis to the case in which we have a small extension (remark 3.2). We want to lift $u$ to a morphism $(R, \xi) \rightarrow\left(A^{\prime}, \eta^{\prime}\right)$. We show that, despite we want a morphism of couple, we only need a morphism of algebras $u^{\prime}: R \rightarrow A^{\prime}$ such that $p u^{\prime}=u$. In fact we have that the condition $F\left(u^{\prime}\right)(\xi)=\eta$ is always satisfied since $\eta^{\prime}$ and $F\left(u^{\prime}\right)(\xi)$ are in $F^{-1}(p)(\eta)$, and this in particular follows by the fact that:

- $F(p)\left(\eta^{\prime}\right)=\eta$ since $p$ is a moprhism of couples
- $F(p)\left(F\left(p u^{\prime}\right)(\xi)\right)=F\left(p u^{\prime}\right)(\xi)=F(u)(\xi)=\eta$ and this holds since the action is transitive (in fact $\exists \sigma \in t_{F} \otimes I$ such that $\left[F\left(u^{\prime}\right)(\xi)\right]^{\sigma}=\eta^{\prime}$ )

We get that, given such a $u^{\prime}, \exists \sigma \in t_{F} \otimes I$ such that $\left[F\left(u^{\prime}\right)(\xi)\right]^{\sigma}=\eta^{\prime}$ and then by the diagram below we get that $v^{\prime}=\left(u^{\prime}\right)^{\sigma}$ satsfies $F\left(v^{\prime}\right)(\xi)=\eta^{\prime}, p v^{\prime}=u$.
We have the following commutative diagram:

In fact, since $t_{F} \otimes I$ acts transitively on $F(p)^{-1}(\eta), \exists \sigma \in t_{F} \otimes I$ such that $\sigma\left(F\left(u^{\prime}\right)(\xi)\right)=\eta^{\prime}$. Now, since $u^{\prime} \in h_{R}(p)^{-1}\left(u^{\prime}\right)$, we get that $\sigma u^{\prime}=v^{\prime} \in h_{R}(p)^{-1}(u)$, i.e. $p v^{\prime}=u$.

Moreover, $F\left(v^{\prime}\right)(\xi)=F\left(\sigma u^{\prime}\right)(\xi)=\sigma\left(F\left(u^{\prime}\right)(\xi)\right)=\eta^{\prime}$, where the last equality follows from the fact that $t_{F} \otimes I$ must commute with the morphism $h_{R} \rightarrow F$ induced by $\xi$.

Now, $u$ factors as $(R, \xi) \rightarrow\left(R_{q}, \xi_{q}\right) \rightarrow(A, \eta)$ for some $q$, thus it is enough to complete the diagram:

or, equivalently, the diagram:

where $w$ has been chosen so as to make the square commute. If the small extension $p r_{1}$ has a section, then $v$ obviously exists (is obtained by composing the section with the projection $R_{q+1} \rightarrow R_{q}$ ). Otherwise, by lemma 3.1(ii), $p r_{1}$ is essential and since the composition is surjective $w$ is a surjection by essentiality (to establish
the existence of $v$ it is enough that $\operatorname{ker}(w) \supseteq J_{q+1}$, so that $w$ factors through $\left.R_{q+1}=S / J_{q+1}\right)$. Now, using $\left(H_{1}\right)$ applied to the projections of $R_{q} \times{ }_{A} A^{\prime}$ on its factors, $\xi \in F\left(R_{q}\right)$ lifts back to $R_{q} \times{ }_{A} A^{\prime}$, so $\operatorname{ker}(w) \supseteq J_{q+1}$, by choice of $J_{q+1}$. Thus $w$ factors through $S / J_{q+1}=R_{q+1}$, and $v$ exists.

This completes the proof that $(R, \xi)$ is a hull of $F$.
$(\Rightarrow)$ Conversely, suppose that a pro-couple $(R, \xi)$ is a hull of $F$.
To verify $\left(H_{1}\right)$, let $p^{\prime}:\left(A^{\prime}, \eta^{\prime}\right) \rightarrow(A, \eta)$ and $p^{\prime \prime}:\left(A^{\prime \prime}, \eta^{\prime \prime}\right) \rightarrow(A, \eta)$ be morphisms of couples, where $p^{\prime \prime}$ is a surjection. Now, since $h_{R} \rightarrow F$ is smooth (it is induced by $\xi$ and we have an hull), then it is also surjective (is a functor map and it is smooth, so we can use the remark). This implies that there exists a $u^{\prime} \in h_{R}$ such that $u^{\prime}:(R, \xi) \rightarrow\left(A^{\prime}, \eta\right)$, and hence by smoothness of $h_{R} \rightarrow F$ applied to $p^{\prime \prime}$, there exists $u^{\prime \prime}:(R, \xi) \rightarrow\left(A^{\prime \prime}, \eta^{\prime \prime}\right)$ rendering the following diagram commutative:

If we consider the following map: $u^{\prime} \times u:(R, \xi) \rightarrow\left(A^{\prime} \times{ }_{A} A^{\prime \prime}, \zeta\right)$, we see that $\zeta=F\left(u^{\prime} \times u^{\prime \prime}\right)(\xi)$ projects onto $\eta^{\prime}$ and $\eta^{\prime \prime}$, so that $\left(H_{1}\right)$ is satisfied.
We can now suppose that $(A, \eta)=(k, e)$, and $A^{\prime \prime}=k[\epsilon]$. In order to show that we have a bijection we show that $\zeta$ is unique. If $\zeta_{1}$ and $\zeta_{2}$ in $F\left(A^{\prime} \times_{k} k[\epsilon]\right)$ we have the same projections $\eta^{\prime}$ and $\eta^{\prime \prime}$ on the factors, then choosing $u^{\prime}$ as above we get morphisms:

$$
u^{\prime} \times u_{i}:(R, \xi) \rightarrow\left(A^{\prime} \times_{k} k[\epsilon], \zeta_{i}\right) \quad \text { for } i=1,2
$$

by smoothness applied to the projection of $A^{\prime} \times_{k} k[\epsilon]$ on $A^{\prime}$.
Since $t_{F} \cong t_{r}$ we have that $u_{1}=u_{2}$, so that also $\zeta_{1}=\zeta_{2}$, which proves $\left(H_{2}\right)$.
Now we know that $t_{R} \cong t_{F}$ and the dimension is finite since $R$ is Noetherian, so $\left(H_{3}\right)$ holds as well.
(2) The necessity of the four conditions is already been proved in a remark.

Suppose now that $F$ satisfies conditions $\left(H_{1}\right)$ to $\left(H_{4}\right)$.
By part (1) we know that $F$ has a hull $(R, \xi)$. We shall prove that $h_{R}(A) \xrightarrow{\sim} F(A)$ by induction on length $(A)$. Consider a small extension $p: A^{\prime} \rightarrow A=A^{\prime} / I$ and assume that $h_{R}(A) \xrightarrow{\sim} F(A)$. For each $\eta \in F(A)$, we have that $h_{R}(p)^{-1}(\eta)$ and $F(p)^{-1}(\eta)$ are both formally principal homogeneous spaces under $t_{F} \otimes I$ (see remark 3.11). Now $h_{R}\left(A^{\prime}\right)$ maps onto $F\left(A^{\prime}\right)$ because it is smooth, so we have $h_{R}\left(A^{\prime}\right) \xrightarrow{\sim} F\left(A^{\prime}\right)$, which proves the induction step.

## Chapter 4

## Deforming Galois Representations

We can finally analyze the work of Barry Mazur about Universal deformation rings ([12]).
Given a continuous homomorphism $\bar{\rho}: G_{\mathbb{Q}, S} \rightarrow \mathrm{GL}_{2}\left(\mathbb{F}_{p}\right)$, the idea is to try to study, in a systematic way, the possible liftings of $\bar{\rho}$ to $p$-adic representations $\rho_{0}: G_{Q, S} \rightarrow \mathrm{GL}_{2}\left(\mathbb{Z}_{p}\right)$.

More precisely, given the following continuous morphism:

$$
\Pi \rightarrow \mathrm{GL}_{N}(A)
$$

we can consider $V=A^{N}$ and we have an action of $\Pi \rightarrow V$ such that, if $\sigma \in \Pi, v \in V$, $\sigma \cdot v=\rho(\sigma) \cdot v \in V$. From this we get an action:

$$
\begin{aligned}
\Pi \times V & \rightarrow V \\
(\sigma, v) & \mapsto \sigma v
\end{aligned}
$$

which is continuous (on one side we have the $m$-adic topology, on the other the pro-finite topology). So, we can view $\rho: \Pi \rightarrow \mathrm{GL}_{N}(A)$ as an action of $\Pi$ on a $\Pi$-module $V=A^{N}$. On the other side, let $W$ be a free $A$-module with the action of $\Pi$ defined as:

- $\forall \sigma \in \Pi, x, y \in W, \sigma(a x+b y)-a(\sigma x)+b(\sigma y)$ for $a, b \in A$
- $\sigma, \tau \in \Pi, x \in W, \sigma(\tau x)=(\sigma \tau) x$
- $1 \Pi x=1$

We can now fix a basis $\left(e_{1}, e_{2}, \ldots e_{N}\right)$ of $W$.
Then, $\forall \sigma \in \Pi, \sigma e_{i}=\sum_{j=1}^{N} a_{j i}(\sigma) \cdot e_{j}$ and by:

$$
\sigma \mapsto\left(a_{i j}(\sigma)\right)_{i, j} \in \mathrm{GL}_{N}(A)
$$

we get:

$$
\rho_{B}: \Pi \rightarrow \mathrm{GL}_{N}(A)
$$

We remark that $\rho_{B}$ depends by the basis, and not only by the module.
We have seen that:

$$
\operatorname{Rep}_{A, N}(\Pi) / \sim \sim \sim\left\{\rho: \Pi \rightarrow \operatorname{GL}_{N}(A)\right\} / \sim
$$

Now, we can consider the category, $\hat{\mathbf{C}}_{k}(A)$, of the Noetherian algebras that are complete, local and such that $A / \mathfrak{m} \cong k$.

Now, if we choose an $N \in \mathbb{N}$ and a residual representation $\bar{\rho}: \Pi \rightarrow \mathrm{GL}_{N}(k)$, we can consider the deformation functor:

$$
\begin{aligned}
D_{\rho}: \hat{\mathbf{C}}_{k}(A) & \rightarrow \text { Sets } \\
A & \mapsto \frac{\operatorname{Hom}_{\bar{\rho}}\left(\Pi, \mathrm{GL}_{N}(A)\right)}{\operatorname{ker}\left(\mathrm{GL}_{N}(A) \rightarrow \mathrm{GL}_{N}(k)\right)}
\end{aligned}
$$

We want to show that this functor is representable, i.e. that $\exists\left(R, \phi_{R}\right) \in \hat{\mathbf{C}}_{k}(A)$ such that $D_{\rho}(-)=\operatorname{Hom}_{k}\left(\left(R, \phi_{R}\right),-\right)$.

Furthermore, we are interested in the automorphisms of this functor. We can view them as a functor:

$$
\begin{aligned}
\operatorname{Aut}\left(D_{\rho}\right): \hat{\mathbf{C}}_{k}(A) & \rightarrow \text { Groups } \\
A & \mapsto \operatorname{Aut}\left(D_{\rho}(A)\right)
\end{aligned}
$$

and we can look at this functor in the following way. For evey $\phi \in D_{\rho}(A)$ we have a module $M(\phi)$ and an associated ring $R=A[\Pi]$, and the automorphisms, viewed as $R$-modules of
$M(\phi)$, are:

$$
\begin{aligned}
\operatorname{Aut}_{R}(M(\phi))=G(\phi) & =\left\{\alpha \in G \mid \alpha \phi=\phi^{\alpha}\right\} \\
& =\left\{\lambda I d_{N}, \lambda \in A^{\times}\right\} \cong \mathbf{G m}(A)
\end{aligned}
$$

where $A^{\times}$is the set of scalars that are units in $A, \mathbf{G m}(A)$ is the multiplicative group of $A$ and the equation on the second line holds if the representation is absolutely irreducible. Thus, we get $\operatorname{Aut}\left(D_{\rho}\right)(A) \cong \mathbf{G m}(A)$.

### 4.1 Deformations

In this section, $\Pi$ will denote a profinite group satisfying the condition $\phi_{p}$, and $k$ will refer to a finite field of characteristic $p$. Let $\hat{\mathbf{C}}$ denote the category of complete Noetherian local rings with residue field $k$. We refer to an object of $\hat{\mathbf{C}}$ as a "local ring in $\hat{\mathbf{C}}$ ", and a morphism of the category is a homomorphism of complete local rings inducing the identity on residue fields. We can finally define the main objects that we will study in this chapter.

Definition 4.1. Let $N$ be a positive integer. If $A$ is a local ring in $\hat{\mathbf{C}}$, two continuous homomorphisms from $\Pi$ to $\mathrm{GL}_{N}(A)$ are strictly equivalent if one can be brought to another by conjugation with an element in the kernel of the reduction map $\mathrm{GL}_{N}(A) \rightarrow \mathrm{GL}_{N}(k)$.

Definition 4.2. A representation of $\Pi$ in $\mathrm{GL}_{N}(A)$ is a strictly equivalence class of continuous homomorphisms from $\Pi$ to $\mathrm{GL}_{N}(A)$. Thus, if $A=k$, a representation is nothing more than a continuous homomorphism. By abouse of notation we will sometimes write $\rho_{0}: \Pi \rightarrow \mathrm{GL}_{N}(A)$ where $\rho_{0}$ is a representation.

Definition 4.3. If $A_{1} \rightarrow A_{2}$ is a morphism in the category $\hat{\mathbf{C}}$ and if $\rho_{1}$ and $\rho_{2}$ are representations of $\Pi$ in $\mathrm{GL}_{N}\left(A_{1}\right)$ and in $\mathrm{GL}_{N}\left(A_{2}\right)$ respectively, we say that $\rho_{1}$ is a deformation of $\rho_{2}$ if any homomorpshim from $\Pi$ to $\mathrm{GL}_{N}\left(A_{1}\right)$ in the strict equivalence class $\rho_{1}$, composed with the induced homomorphism $\mathrm{GL}_{N}\left(A_{1}\right) \rightarrow \mathrm{GL}_{N}\left(A_{2}\right)$, yields a homomorpshim in the strict equivalence class $\rho_{2}$.

Definition 4.4. A residual representation of dimension $N$ is a continuous homomor$\operatorname{phism} \bar{\rho}: \Pi \rightarrow \mathrm{GL}_{N}(k)$, i.e. a representation of $\Pi$ in $\mathrm{GL}_{N}(k)$.

Two residual representations are equivalent if one can be brought into the other by conjugation by an element in $\mathrm{GL}_{N}(k)$; they are twist equivalent if one, after tensoring with a suitable one-dimensional representation, can be made equivalent to the other.

### 4.2 Cohomological interpretation of the Zariski tangent space

For this section we refer to [3].
One of the basic tools of deformation theory is the cohomological interpretation of the Zariski tangent space. This allows us to "control" the somewhat abstract universal deformation rings that occur by means of concrete cohomological calculations.

Let $\Pi$ satisfy the $p$-finiteness condition as above, $\bar{\rho}: \Pi \rightarrow \mathrm{GL}_{N}(k)$ a continuous residual representation with $k$ a finite field of characteristic $p$, and $\Lambda$ a coefficient-ring with residue field $k$. We fix an homomorphism $\rho: \Pi \rightarrow \mathrm{GL}_{N}(A)$, and we consider the deformation problem relative to $\rho$, i.e. the functor:

$$
D_{\rho}: \hat{\mathbf{C}}_{\Lambda}(A) \rightarrow \text { Sets }
$$

More specifically, we consider the Zariski tangent $A$-module, $t_{D_{\rho}, A}$, which we will denote by $t_{\rho}$.

Following the idea sketched in the introduction to this chapter, we interpret it from a cohomological point of view. Let $V$ be the free $A$-module of rank $N$, i.e. $V=A^{N}$, endowed with an $A$-linear action given via composition of $\rho: \Pi \rightarrow \mathrm{GL}_{N}(A)$ with the natural action of $\mathrm{GL}_{N}(A)$ on $V$. Let now $\operatorname{End}_{A}(V)$ denote the free $A$ module (of rank $N^{2}$ ) consisting of $A$-linear endomorphisms of $V$. The action of $\Pi$ on $V$ induces an action, the adjoint action,
of $\Pi$ on $\operatorname{End}_{A}(V)$ given by the formula:

$$
(\sigma \cdot e)(v)=\rho(\sigma)\left(e\left(\rho(\sigma)^{-1}(v)\right)\right.
$$

where $\sigma \in \Pi, e \in \mathrm{E}_{A}(V)$ and $v \in V$.

Proposition 4.1. There is a natural isomorphism of $A$-modules

$$
t_{\rho} \cong H^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)
$$

Proof. Let $\Gamma:=\operatorname{ker}\left\{\mathrm{GL}_{N}(A[\epsilon]) \rightarrow \mathrm{GL}_{N}(A)\right\}$, we have the following short exact sequence of groups:

$$
1 \longrightarrow \Gamma \longrightarrow \mathrm{GL}_{N}(A[\epsilon]) \longrightarrow \mathrm{GL}_{N}(A) \longrightarrow 1
$$

Since we can rewrite every element $T \in \mathrm{GL}_{N}(A)$ as $T=I d+\epsilon M_{N}(A)$, we notice that we have an injection $\mathrm{GL}_{N}(A) \subset \mathrm{GL}_{N}(A[\epsilon])$, from which we derive a natural splitting.
In this way, we can view $\mathrm{GL}_{N}(A[\epsilon])$ as a semidirect product $\mathrm{GL}_{N}(A) \ltimes \Gamma$.
In fact, if we consider:

$$
\begin{aligned}
\mathrm{GL}_{N}(A[\epsilon]) & \rightarrow \Gamma \times \mathrm{GL}_{N}(A) \\
u & \mapsto\left(u \phi(u)^{-1}, \phi(u)\right)
\end{aligned}
$$

where we notice that:

$$
\phi\left(u \phi(u)^{-1}\right)=\phi(u) \phi(u)^{-1}=1
$$

Moreover, letting $M_{N}(A)$ denote the underlying additive group of the $A$-algebra of $N \times N$ matrices with entries in $A$, there is a natural isomorphism of commutative groups:

$$
\begin{aligned}
\Gamma=1+\epsilon \cdot M_{N}(A) & \cong M_{N}(A) \cong \operatorname{End}_{A}(V) \\
1+\epsilon \cdot m & \mapsto m
\end{aligned}
$$

Therefore, using these isomorphisms, one may rewrite $\mathrm{GL}_{N}(A[\epsilon])$ as the semi-direct product:

$$
\operatorname{GL}_{N}(A[\epsilon]) \cong \mathrm{GL}_{N}(A) \ltimes M_{N}(A)
$$

where the action of $\mathrm{GL}_{N}(A)$ on $M_{N}(A)$ is the standard adjoint action (i.e. it is by conjugation).

Now, if we consider the set $D_{\rho}(A[\epsilon])$ of deformations lifting $\rho$ to $A[\epsilon]$, we have that this is the set of equivalence classes (relative to $\rho$ ) of homomorphisms $\rho^{\prime}: \Pi \rightarrow \mathrm{GL}_{N}(A[\epsilon])$ fitting into the diagram:

where the composition is $\rho$.
Since we are considering the case of strict equivalence and we have an action of $\Gamma \subset$ $\mathrm{GL}_{N}(A[\epsilon])$, once we fix a $\rho_{0}$ we can obtain every $\rho^{\prime}$ by conjugation: $\rho^{\prime}=\gamma \rho \gamma^{-1}$. For any other $\rho^{\prime}$, we define the difference cocycle:

$$
\begin{gathered}
c_{\rho^{\prime}}: \Pi \rightarrow \Gamma \cong \operatorname{End}_{A}(V) \\
c_{\rho^{\prime}}(g)=\rho^{\prime}(g) \cdot \rho_{0}(g)^{-1} \in \Gamma \quad \text { for } g \in \Pi
\end{gathered}
$$

where in particular we notice that $\rho^{\prime}(g) \in \mathrm{GL}_{N}(A[\epsilon])$ and $\rho_{0}(g)^{-1} \in \mathrm{GL}_{N}(A)$, so the product is actually in $\Gamma$. Moreover, this is actually a cocycle, i.e. it satisfies the property:

$$
c_{\rho^{\prime}}\left(g_{1} g_{2}\right)=c_{\rho^{\prime}}\left(g_{1}\right) c_{\rho^{\prime}}\left(g_{2}\right)^{g_{1}}
$$

In fact we have that:

$$
\begin{aligned}
c_{\rho^{\prime}}\left(g_{1} g_{2}\right) & =\rho^{\prime}\left(g_{1} g_{2}\right) \cdot \rho_{0}\left(g_{1} g_{2}\right)^{-1}=\rho^{\prime}\left(g_{1}\right) \rho^{\prime}\left(g_{2}\right) \rho_{0}\left(g_{2}\right)^{-1} \rho_{0}\left(g_{1}\right)^{-1}= \\
& =\rho^{\prime}\left(g_{1}\right) c_{\rho^{\prime}}\left(g_{2}\right) \rho_{0}\left(g_{1}\right)^{-1}=\rho^{\prime}\left(g_{1}\right) \rho_{0}\left(g_{1}\right)^{-1} \rho_{0}\left(g_{1}\right) c_{\rho^{\prime}}\left(g_{2}\right) \rho_{0}\left(g_{1}\right)^{-1}= \\
& =c_{\rho^{\prime}}\left(g_{1}\right) c_{\rho^{\prime}}\left(g_{2}\right)^{g_{1}}
\end{aligned}
$$

This proves that we have a bijection between the set of liftings $\rho^{\prime}$ of $\rho$, and the set $Z^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)$ of 1 - cocycles on $\Pi$ with the values in the $\Pi$-module $\operatorname{End}_{A}(V) \cong M_{N}(A)$, where the action of $\Pi$ on $\operatorname{End}_{A}(V)$ is the adjoint action as described above. So we have construct a map:

$$
\left\{\rho^{\prime}: \Pi \rightarrow \operatorname{GL}_{N}(A[\epsilon])\right\} \rightarrow Z^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)
$$

Under this bijection, liftings $\rho^{\prime}$ and $\rho^{\prime \prime}$ of $\bar{\rho}$ are strictly equivalent if and only if their associated cocycles $c_{\rho^{\prime}}$ and $c_{\rho^{\prime \prime}}$ are cohomologous. In fact, we know that if $N \in M_{N}(A)$, then the element $(1+N \epsilon)^{-1}=(1+N \epsilon) \in \mathrm{GL}_{N}(A[\epsilon])$, so it follows that the cocycles given by $\rho^{\prime}$ and $\rho^{\prime \prime}=(1+N \epsilon) \rho(1-N \epsilon)^{-1}$ differ by the cobundary $N-g N$. We remark that, since this process can be reversed, we have injectivity.

We get:

$$
\left\{\rho^{\prime}: \Pi \rightarrow \mathrm{GL}_{N}(A[\epsilon])\right\} / \Pi \rightarrow \frac{Z^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)}{B^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)}=H^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)
$$

We can now state the following proposition:

Proposition 4.2. Let $A$ be an Artinian coefficient $\Lambda$-algebra. Then the Zariski tangent $A$-module $t_{\rho}$ is finite.

Proof. Let $A$ be Artinian. From the proposition before it is enough to show that the $A$ module $H^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)$ is finite.

Let $\Pi_{0} \subset \Pi$ be the kernel of $\rho$. Since $A$ is Artinian, $\Pi_{0}$ is an open subgroup of finite index in $\Pi$.

The $A$-module $H^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)$ fits into an exact sequence:

$$
H^{1}\left(\Pi / \Pi_{0}, \operatorname{End}_{A}(V)\right) \longrightarrow H^{1}\left(\Pi, \operatorname{End}_{A}(V)\right) \longrightarrow \operatorname{Hom}\left(\Pi_{0}, \operatorname{End}_{A}(V)\right)
$$

Now, the $A$-module $H^{1}\left(\Pi / \Pi_{0}, \operatorname{End}_{A}(V)\right)$ is finite since both $\Pi / \Pi_{0}$ and $\operatorname{End}_{A}(V)$ are finite. On the other hand, also $\operatorname{Hom}\left(\Pi_{0}, \operatorname{End}_{A}(V)\right)$ is finite, since $\Pi$ satisfies the $p$-finiteness condition. It follows that $H^{1}\left(\Pi, \operatorname{End}_{A}(V)\right)$ is finite.

### 4.3 The Main Theorem

We want to establish the existence of a universal deformation of any absolutely irreducible $N$-dimensional residual representation $\bar{\rho}$. Specifically, there is a complete Noetherian local ring $R=R(\Pi, k, \bar{\rho}) \in \hat{\mathbf{C}}$ with residue field $k$, together with a deformation: $\boldsymbol{\rho}: \Pi \rightarrow \mathrm{GL}_{N}(R)$ of $\bar{\rho}$ which is universal in the sense that for any $A \in \hat{\mathbf{C}}$ and deformation $\rho_{0}$ of $\bar{\rho}$ to $A$, there is a unique morphism $R \rightarrow A$ in $\hat{\mathbf{C}}$ such that the induced homomorphism $\mathrm{GL}_{N}(R) \rightarrow \mathrm{GL}_{N}(A)$ brings $\boldsymbol{\rho}$ to $\rho_{0}$. We shall show that the pair $(R, \boldsymbol{\rho})$ is determined up to canonical isomorphism by the twist-equivalence class of $\bar{\rho}$.

### 4.3.1 Statement

Proposition 4.3 (Existence and uniqueness). (a) If $\bar{\rho}$ is absolutely irreducible, a universal deformation ring $R=R(\Pi, k, \bar{\rho})$ and a universal deformation $\boldsymbol{\rho}$ of $\bar{\rho}$ to $R$ exist. The pair $(R, \boldsymbol{\rho})$ is uniquely determined up to canonical isomorphism by the twist-equivaence class of $\bar{\rho}$ in the following sense:

Given two twist-equivalent residual representations $\bar{\rho}$ and $\overline{\rho^{\prime}}$, there is a canonical isomorphism

$$
r\left(\overline{\rho^{\prime}}, \bar{\rho}\right): R(\Pi, k, \bar{\rho}) \xrightarrow{\sim} R\left(\Pi, k, \overline{\rho^{\prime}}\right)
$$

bringing the universal deformation $\boldsymbol{\rho}$ of $\bar{\rho}$ to the universal deformation $\rho^{\prime}$ of $\overline{\rho^{\prime}}$. The system of canonical isomorphisms have the homomorphic property:
(i) $r(\bar{\rho}, \bar{\rho})$ is the identity, for all $\bar{\rho}$
(ii) $r\left(\overline{\rho^{\prime \prime}}, \overline{\rho^{\prime}}\right) \times r\left(\overline{\rho^{\prime}}, \bar{\rho}\right)=r\left(\overline{\rho^{\prime \prime}}, \bar{\rho}\right)$
(b) If $\bar{\rho}$ is not absolutely irreducible, then a "versal" deformation of $\bar{\rho}$ exists, i.e. there is a hull. This means that we can find an object $R \in \hat{C}$ and a deformation $\boldsymbol{\rho}$ of $\bar{\rho}$ to $R$ such that any deformation $\rho_{0}$ of $\bar{\rho}$ to any object $A$ in $\hat{\boldsymbol{C}}$ is induced by a not necessarily unique morphism $R \rightarrow A$ of $\hat{\boldsymbol{C}}$; however, if $A$ is the "dual numbers" $k[\epsilon]$, the morphism $R \rightarrow A$ bringing $\boldsymbol{\rho}$ to $\rho_{0}$ is unique.
The isomorphism-type of the hull $R$ is unique, but $R$ itself is not determined up to canonical isomoprhism.

### 4.3.2 Preliminary results

We are going to prove only the existence of universal and versal deformation ring.
Before actually proceed with the proof we are going to state some preliminary results that will be used for proving our statement.
Let $A_{0}, A_{1}, A_{2}, A_{3}$ Artinian rings in $\hat{\mathbf{C}}$ such that $A_{3} \cong A_{1} \times{ }_{A_{0}} A_{2}$, i.e. we get the following cartesian diagram:

Suppose now that $A_{1} \rightarrow A_{0}$ is a small extension, i.e. a surjective map whose kernel is a nonzero principal ideal $(t)$ such that $\mathfrak{m}_{A_{1}} \cdot(t)=0$.
Let:

$$
E_{i}=\operatorname{Hom}_{\bar{\rho}}\left(\Pi, \operatorname{GL}_{N}\left(A_{i}\right)\right) \quad \text { for } i=0, \ldots, 3
$$

where $\bar{\rho}$ means continuous homomorphisms which are liftings of $\bar{\rho}$.
Set

$$
G_{i}=\operatorname{ker}\left(\mathrm{GL}_{N}\left(A_{i}\right) \rightarrow \mathrm{GL}_{N}(k)\right) \quad \text { for } i=0, \ldots, 3
$$

We recall that an element of $G_{i}$ is of the from $I d_{N}+M_{N \times N}\left(\mathfrak{m}_{A}\right)$.
$G_{i}$ acts naturally on $E_{i}$ by conjugation of the range $\mathrm{GL}_{N}\left(A_{i}\right)$ and the orbit-space $E_{i} / G_{i}$ may be indetified with the space of deformations of $\bar{\rho}$ to $A_{i}$.

Since $E_{i}$ is functorial, we get the natural morphism:

$$
b: E_{3} / G_{3} \rightarrow E_{2} / G_{2} \times_{E_{0} / G_{0}} E_{1} / G_{1}
$$

We are now going to state five important lemmas that will be used in the proof of the main theorem (see [10] for more details).

Lemma 4.4. If $\alpha: A_{1} \rightarrow A_{0}$ is surjective, then it induces a surjection $\alpha: G_{1} \rightarrow G_{0}$.

Proof. Let $\alpha: A_{1} \rightarrow A_{0}$ be surjective, then, since we have local rings, it follows that the induced group homomorphism $\alpha: \operatorname{GL}_{N}\left(A_{1}\right) \rightarrow \operatorname{GL}_{N}\left(A_{0}\right)$ is surjective. We use the notation $i_{j}: \mathrm{GL}_{N}\left(A_{j}\right) \rightarrow \mathrm{GL}_{n}(k)$ for $j=0,1$.
For $Y \in G_{0}$, we want to show that it comes from an $X \in G_{1}$. Since $Y \in G_{0}$ it follows by definition that $i_{0}(Y)=I_{N}$. Now, using the surjectivity of $\alpha$, we get that $\exists X \in \mathrm{GL}_{N}\left(A_{1}\right)$ such that $\alpha(X)=Y$.

Using the fact that $\alpha$ is a morphism in the category, we know that $i_{0} \cdot \alpha=i_{1}$, hence $i_{1}(X)=i_{0}(\alpha(X))=i_{0}(Y)=I_{n}$ and $X \in G_{1}$.

Lemma 4.5. Since the map $G_{1} \rightarrow G_{0}$ is surjective, it follows that $b$ is surjective.

Proof. Let $\left(\left[a_{2}, a_{1}\right]\right) \in E_{2} / G_{2} \times{ }_{E_{0} / G_{0}} E_{1} / G_{1}$ and let $\alpha_{i}: A_{i} \rightarrow A_{0}$ for $i=1,2$. Using the definition of fiber product, we have that $\left[\alpha_{1}\left(a_{1}\right)\right]=\left[\alpha_{2}\left(a_{2}\right)\right]$ in $E_{0} / G_{0}$, i.e. there exists $X \in G_{0}$ such that $\alpha_{1}\left(a_{1}\right)=X \alpha_{2}\left(a_{2}\right) X^{-1}$. Since $\alpha_{2}$ is surjective, applying the previous lemma we get that $\alpha_{2}: G_{2} \rightarrow G_{0}$ is also a surjection. It follows that there exists $X_{2} \in G_{2}$
with $\alpha_{2}\left(X_{2}\right)=X$. Thus $\alpha_{1}\left(a_{1}\right)=\alpha_{2}\left(X_{2} a_{2} X_{2}^{-1}\right)$. Therefore $\left(a_{1}, X_{2} a_{2} X_{2}^{-1}\right) \in E_{3} / G_{3}$ and

$$
\left.b\left(\left[\left(a_{1}, X_{2} a_{2} X_{2}^{-1}\right)\right]\right)=\left(\left[X_{2} a_{2} X_{2}^{-1}\right],\left[a_{1}\right]\right)=\right)\left[a_{2}, a_{1}\right]
$$

Let $\pi_{1}$ denote an element in $E_{1}$ and $\pi_{0}$ its image in $E_{0}$. Set $G_{i}\left(\pi_{i}\right)$ to be the subgroup of $G_{i}$ consisting of all elements commuting with the image of $\pi_{i}$ in $\mathrm{GL}_{N}\left(A_{i}\right)$, for $i=0,1$.

Lemma 4.6. If, for all $\pi_{2} \in E_{2}$ the natural mapping $G_{2}\left(\pi_{2}\right) \rightarrow G_{0}\left(\pi_{0}\right)$ is surjective, then $b$ is injective.

Proof. Let $\beta_{i}: A_{3} \rightarrow A_{i}$ for $i=1,2$.
Let $\pi_{3}, \tilde{\pi}_{3} \in E_{3}$, with:

$$
\left(\left[\pi_{2}\right],\left[\pi_{1}\right]\right)=b\left(\left[\pi_{3}\right]\right)=b\left(\left[\tilde{\pi}_{3}\right]\right)=\left(\left[\tilde{\pi}_{1}\right],\left[\tilde{\pi}_{3}\right]\right)
$$

where $\pi_{1}=\beta_{1}\left(\pi_{3}\right), \pi_{2}=\beta_{2}\left(\pi_{3}\right), \tilde{\pi}_{1}=\beta_{1}\left(\tilde{\pi}_{3}\right)$ and $\tilde{\pi}_{2}=\beta_{2}\left(\tilde{\pi}_{3}\right)$. Then there exist $X_{1} \in G_{1}$ and $X_{2} \in G_{2}$ with $X_{1} \pi_{1} X_{1}^{-1}=\tilde{\pi}_{1}$ and $X_{2} \pi_{2} \pi_{2}^{-1}=\tilde{\pi}_{2}$. Let now $\bar{X}_{1}, \bar{X}_{2}$ be the images under $\alpha_{1}, \alpha_{2}$ of $X_{1}$ and $X_{2}$ in $G_{0}$.
Let $\pi=\alpha_{1}\left(\pi_{1}\right)=\alpha_{2}\left(\pi_{2}\right)$ and $\tilde{\pi}=\alpha_{1}\left(\tilde{\pi}_{1}\right)=\alpha_{2}\left(\tilde{\pi}_{2}\right)$. Then, we get $\bar{X}_{1} \pi \bar{X}_{1}^{-1}=\tilde{\pi}=\bar{X}_{2} \pi \bar{X}_{2}^{-1}$ and $\bar{X}_{2}^{-1} \bar{X}_{1} \in G_{0}\left(\pi_{0}\right)$.
By hypothesis, there exists $Y \in G_{2}\left(\pi_{2}\right)$ with $\bar{Y}=\bar{X}_{2}^{-1} \bar{X}_{1}$. Let $\tilde{X}_{2}=X_{2} Y$, then we get:

$$
\tilde{X}_{2} \pi_{2} \tilde{X}_{2}^{-1}=X_{2} Y \pi_{2} Y^{-1} X_{2}^{-1}=X_{2} \pi_{2} X_{2}^{-1}=\tilde{\pi}_{2}
$$

and

$$
\overline{\tilde{X}}_{2}=\bar{X}_{2} \bar{Y}=\bar{X}_{2} \bar{X}_{2}^{-1} \bar{X}_{1}=\bar{X}_{1}
$$

Thus $X_{1}$ and $\tilde{X}_{2}$ define an element $X_{3}$ in $G_{3}$ and we get $X_{3} \pi_{3} X_{3}^{-1}=\tilde{\pi}_{3}$. Hence $\left[\pi_{3}\right]=\left[\tilde{\pi}_{3}\right]$ in $E_{3} / G_{3}$.

Lemma 4.7. If $A_{0}=k$ and $A_{2}=k[\epsilon]$ for $\epsilon^{2}=0$, then the map $b$ is injective.

Proof. Let $\pi_{2} \in E_{2}$. Since $A_{0}=k$ by hypothesis and $\alpha_{2}\left(\pi_{2}\right)=\rho$, we have that $G_{0}=G(k)=$ $\left\{I_{n}\right\}$, and thus $G_{0}(\rho)=\left\{I_{n}\right\}$. Hence the map $G_{2}\left(\pi_{2}\right) \rightarrow G_{0}(\rho)$ is surjective. Applying the previous lemma we get that $b$ is injective.

Lemma 4.8. If $\bar{\rho}$ is absolutely irreducible, then $G_{i}(\pi)$ consists in the subgroup of scalar matrices in $G_{i} \subset \mathrm{GL}_{N}\left(A_{i}\right)$ for $i=0,1$.

Proof. Given $\rho: \Pi \rightarrow \operatorname{GL}_{N}(A)$ we can consider the group $M=A^{N}$ and view it as a ring $R=A[\Pi]$ so that saying that $\bar{\rho}$ is irreducible is equivalent to say that it is simple.

Now, let $\gamma \in G_{0}\left(\pi_{0}\right)$ : we can view $\gamma$ as a matrix in $\mathrm{GL}_{N}\left(A_{0}\right)$ that gives us a morphism $M \rightarrow M$; in particular, if it commutes with $\pi_{0}$, it is a $R$-modules morphism. Thus, since it is a non-zero morphism of $R$-modules, it is an isomoprhism by Schur's Lemma. Now, in order to be isomoprhic as $\Pi$-module, $G_{i}(\pi)$ has to be a scalar.

### 4.3.3 Proof of the Theorem

We can finally prove our Theorem.

Proof. Following the construction and the notation above, we want to prove our Theorem by showing that the Schlessinger criterion holds.

With the first two preliminary lemmas, we have already shown that, since $A_{1} \rightarrow A_{0}$ is small extension, our functor $b$ is a surjection, and condition $\left(H_{1}\right)$ always holds.

On the other hand, using the results in the section of the Zariski tangent space, we know that also condition $\left(H_{3}\right)$ always holds.

In order to prove that $\left(H_{2}\right)$ holds, we have to show that the functor is bijective if $A_{0}=k$ and $A_{2}=k[\epsilon]$. We already know that the surjectivity holds, so under those assumption it is enough to prove that $b$ is injective. This follows from lemma 4.7.

To complete our proof we just need to check that $\left(H_{4}\right)$ holds when $\bar{\rho}$ is absolutely irreducible. If $\bar{\rho}$ is absolutely irreducible, lemma 4.8 implies that the morphism in lemma 4.6 is surjective
for all surjective maps $A_{1} \rightarrow A_{0}$, hence $\left(H_{4}\right)$ follows.
If $\bar{\rho}$ is absolutely irreducible, we refer to $R=R(\pi, k, \bar{\rho})$ as the universal deformation ring of $\bar{\rho}$. The universal deformation ring is unique in the sense that it is determined up to canonical isomorphism. In the more general case in which $\bar{\rho}$ is not necessarily absolutely irreducible, the "versal deformation ring" $R$ is determined up to (noncanonical) isomorphism (which induces the "identity mapping" on Zariski tangent space).
Having obtained the universal deformation ring $R$, it is now easy to construct the universal deformation $\boldsymbol{\rho}$. In particular, for evey power of the maximal ideal $\mathfrak{m}$ of $R$, we have a deformation $\rho_{n}$ of $\bar{\rho}$ to $R / \mathfrak{m}^{n}$ which can be realized by a compatible family of liftings $r_{n}: \Pi \rightarrow$ $\mathrm{GL}_{N}\left(R / \mathfrak{m}^{n}\right)$, using the surjectivity of the homomorphisms $\mathrm{GL}_{N}\left(R / \mathfrak{m}^{n+1}\right) \rightarrow \mathrm{GL}_{N}\left(R / \mathfrak{m}^{n}\right)$. The universal deformation $\boldsymbol{\rho}$ of $\bar{\rho}$ is then just the strict equivalence class of the inverse limit $\lim _{\rightleftarrows} r_{n}$.
