# Abstract <br> The Socioeconomic Determinants of Correlations Between Stock Market Returns as Revealed by a Gravity Model 

## Danni Yang

Economic variants of Newton's law of universal gravitation have been used to model the flow of trade between two countries as proportional to the attraction created by measures of their economic masses and dampened by their distance from one another. More business will likely take place between big economies that are close to one another. This study uses that same gravity analogy to explore the long-term, or perhaps more accurately, stable determinants of the correlation of stock markets, where in its simplest form, financial mass is represented by the joint market size of two countries and financial distance by the overlap in trading hours of their stock exchanges. Stock market correlations are found to be positively related to these variables and negatively related to joint trading volume. If distance is expanded to include the relative similarity in culture and legal institutions, it is found that correlations are positively related to the disparity in religious pluralism, negatively related to differences in economic freedom, and positively related to the sharing of a common legal system. In all, the gravity models estimated explain almost 11 percent of the cross-sectional variation in the correlations of stock markets, with the incremental influence of the cultural and legal variables being many times greater than that of the financial variables.

## Acknowledgments

I would like to express my gratitude to all those who gave me the opportunity to complete this thesis. I am deeply indebted to my supervisor, Dr. Gregory Lypny, Department of Finance, John Molson School of Business, whose direction, stimulating suggestions and encouragement helped me through the research and writing. I would especially like to express thanks to my mom whose patience, care and love enabled me to complete this work.

## 1. Introduction

What characteristics of countries explain the co-movement of returns in their stock markets? In Newtonian physics, the gravitational attraction between two objects is positively related to their masses, or more specifically, the product of their masses, and negatively related to their distance from one another. Economists borrowed Newton's law of universal gravitation in the 1960s, among them Tinbergen (1962), Poyhonen (1963) and Linnemann (1966), to model trade flows, using measures such as aggregate income to represent economic mass, and geographic distance to represent physical distance. Subsequent studies eventually came to include variables about culture, or those which can be connected to culture - borders, language, legal origin - ostensibly refining the notion of distance and turning it into a continuum of similarity to dissimilarity. A small number have also looked at stock market linkages, but the finance literature has generally not paid much attention to uncovering the more stable or long-term determinants of the correlation of stock markets of different countries, and has instead concerned itself with studying the time-varying properties of return covariances using relatively high frequency data.

This study explores the association between gravity factors and the stock market correlations of 18 Asia-Pacific countries. The motivation is to complement the research on the short-run, time-varying properties of return covariances by providing a sense of the factors that are tied to long-term differences in level or that may result in more permanent shifts when they change. We find that overlapping stock market trading hours are a good proxy for distance narrowly defined. Joint trading volume and religious diversity also play a part, as does legal origin and economic freedom.

## 2. Background

Research using gravity models to explain bilateral trade flows, with GDP standing in for mass and geographic distance for the physical distance between countries, can be found in Bergstrand (1985) and Feenstra, Markusen and Rose (2001). Bergstrand (1985) found that GDP deflators improve the explanatory power of the models, pointing to the need for measuring mass appropriately through the incorporation of real values. Feenstra, Markusen, and Rose (2001) found evidence of reciprocal dumping in assessing the "home market effect" in separate gravity equations for differentiated and homogeneous goods. The home market effect is present for differentiated goods but not homogeneous goods. Their result is consistent with the theoretical predictions of reciprocal dumping playing a role in homogeneous markets. McCallum (1995) introduced the common border as an alternative distance measure to explain the regional trade patterns between the US and Canada and found that borders have a significant association with trade patterns. Rauch (2001) found that cultural ties based on ethnicity or religion are associated with the correlations of economic activity.

Financial economics has tended to focus less on the long-term determinants of correlations and more on the time-varying properties of stock market linkages as exemplified in studies using GARCH estimations. The motivation for this is that if investors can forecast changes in joint distributions of returns, then they will be able to make better portfolio investment and risk management decisions. Longin and Solink (1995) used a bivariate GARCH model to capture the conditional covariance structure of monthly international equity returns from 1960 to 1990 and found significant time-variation. Har-
vey (1995) used a one-factor asset pricing model to estimate time-varying capital market correlation. Ramchand and Susmel (1998) used an SW-ARCH model to show that correlations were both time- and state-dependent and that the covariance structure between markets changes over time, with implications for portfolio diversification strategies. Bodart and Reding (1999) also used a bivariate GARCH model to examine the impact of exchange rate variability on international correlations, while Groenan and Franses (2000) used a graphing technique to investigate stock market correlations and their evolution over time. It is now well accepted that the volatility and correlation of rates of return of many financial assets varies over time.

Only recently has attention turned to the longer-term determinants of international securities correlations, and as physical transportation is generally not a fundamental variable in financial markets, the door was opened to exploring alternatives, such as measures of socioeconomic and cultural similarity, to geographical distance in gravity models in addition to conventional financial variables. Portes and Rey (2002) studied the bilateral equity flows of 14 OECD countries from 1989 to 1996 and uncovered a geographical pattern of international asset transactions. Distance can proxy information costs and other variables that represent differences in information, transaction timeliness and technology. Distance enters in the equation as a proxy for information asymmetries and other variables which plausibly represent international information flows (telephone traffic, number of bank branches, index of insider trading were also significant). They interpret their findings as financial markets segmented by such informational asymmetries or familiarity. This, in turn, provides a possible reason for the home equity bias. Flavin, Harley and Rousseou (2002) used a gravity model to explain the stock market correlations in 27 in-
dustrial countries using 1999 data, and found that overlapping stock market opening hours and a common border, in particular, tend to be associated with stock market correlation. The number of non-overlapping trading hours restricts the ability of investors in different markets to react to 'global news' simultaneously (or with shorter time lags), and discourages them from venturing from home. Huang (2006) used a gravity model to measure stock market correlations for 20 emerging industrial countries from 1995 to 2002, and found that distance, market size and legal system similarity are significantly related to stock market correlations.

The correlatedness of returns across stock markets can be thought as the degree to which markets are integrated. Research has documented an increase in international economic and financial integration. Heaney et al (2002), using monthly US dollar stock returns from 1985 to 2001, found that Latin American stock markets have become more integrated. Their finding reflects the growing cooperation between Latin American countries since the liberalization of their stock markets in the early 1990s. Prior to liberalization, equity markets tended to be more correlated with the world market portfolio than regionally. Morgado and Tavares (2006) found that stock markets have became more correlated, and that this increase in correlation is associated with bilateral economic integration and segmentation factors such as mutual participation in a trade agreement.

## 3. Data and Methods

### 3.1 Base gravity model

A gravity model as applied to trade flows, $F$, poses a positive relation to the economic mass of two countries, $M_{i}$ and $M_{j}$, measured, for example, by GDP, and a negative relation to their geographic distance $D_{i j}$ as in

$$
F_{i j}=k \frac{M_{i} M_{j}}{D_{i j}}
$$

where $k$ is a constant. The model is linearized by taking the natural logarithm of each side. Holding $\mathrm{M}_{\mathrm{i}}$ and $\mathrm{D}_{\mathrm{ij}}$ constant, the bigger $M_{j}$, the bigger the trade flows between two countries. In financial markets, this mass-distance analogy is melded into similaritydissimilarity. The base model used in this study is

$$
\begin{align*}
\rho_{i j t}=\beta_{0} & +\beta_{1} \ln (G C D)+\beta_{2} \text { Border } \\
& +\beta_{3} \ln \left(C M C_{i t} \cdot C M C_{j t}\right)+\beta_{4} \ln \left(\text { Volume }_{i t} \cdot \text { Volume }_{j t}\right)+\beta_{5} \text { Legal }_{i j}+\varepsilon_{i j t} \tag{1}
\end{align*}
$$

The dependent variable is the Pearson correlation coefficient for the total monthly returns on the major stock market indices of country $i$ and $j$, sampled from 2002 to 2007 for 18 Asia-Pacific Economic Cooperation (APEC) members: Australia, Canada, Chile, China, Hong Kong, Indonesia, Japan, Malaysia, Mexico, New Zealand, Peru, Philippines, Russia, Singapore, South Korea, Taiwan, Thailand, and the United States. The 72 return observations for each country are collected from Bloomberg. The error term is assumed to be normally distributed with a zero mean and standard deviation equal to one. The model is estimated by ordinary least squares. The independent variables discussed below capture geographic and socioeconomic similarity.

The first independent variable, $G C D$, is the natural logarithm of geographic distance between the financial centers of two countries as measured by the great circle between them. The great circle distance is obtained from Direct-line Distance by Fitzpatrick and Modlin (1986). It is defined as the shortest distance between two points on a spheroid, and can be estimated by air flight duration. With proximity comes more frequent contact, familiarity, exchange of ideas, intermingling of values, and I hypothesize, greater similarity in financial behavior, which in turn implies more highly correlated stock markets. Figure 1 shows a histogram of the flight durations for the 153 different trips that could be taken between the 18 countries in the sample. The figure shows that there is enough variation in flight durations to justify inclusion of $G C D$ as an explanatory variable. One-half of the trips can be made in a working day and one-fifth in three hours or less. I predict that the correlations will be higher between these countries, all things being equal. Table 1 reports the great circle distances in kilometers, and Figure 2 shows selected "flight paths" between financial centres in Canada, China, Australia and Chile as a visual representation of great circle distances.

Figure 2 - Great Circle Distance

Source: $\mathrm{htp}: / / g c . \mathrm{kls} 2 . \mathrm{com} /$. The great circle distances between Ontario, Shanghai, Sydney and Santiago.

The variable Border flags whether two countries are neighbours, taking the value 1 if they share a common border or strait and 0 otherwise. Eighteen pairs of countries share at least one border or strait, while Indonesia and Malaysia share as many as four with other countries. The stock markets of countries with a common border or strait are expected to be more highly correlated. Table 2 reports which countries are neighbours.

Legal is a dummy variable equal to one if the two countries' legal systems have the same historical origin and zero otherwise. La Porta et al. (1998) argue that most modern legal systems can be traced back to one of four major families of law: English common law, French civil law, German civil law, or Scandinavian civil law. Table 3 reports the origin of the legal system of each country in our sample.

Table 3 - Legal origins

| English common law | French civil law | German civil law |
| :---: | :---: | :---: |
| US | Philippines | Scandinavian civil law |
| Hong Kong | Indonesia | Taiwan |
| Singapore | Mexico | South Korea |
| Thailand | Chile |  |
| Australia | Peru |  |
| New Zealand |  |  |
| Malaysia |  |  |
| Canada |  |  |

Legal systems are classified as four major families of law: English common law, French civil law, German civil law, or Scandinavian civil law. China (Socialist origin) and Russia (Russian origin) do not belong to any of these four legal origins.

I predict that the stock markets of countries whose current legal systems have the same origin will be more highly correlated, all things being equal. This is because similar legal systems are more likely to produce similar regulatory environments, rules of corporate governance, and even investment climates, which in turn reduces contracting costs and information asymmetries between them and also implies that they are more likely to face similar systematic risks. Legal rules protecting investors vary systematically among legal origins. Common law countries are more protective of outside investors than civil law countries and particularly French civil law countries. The popular pressLegal Affairs has attributed the differences in the economic success of Malaysia and Indonesia and the effectiveness of their individual responses to financial crises to specific
actions and contemporary institutions but these can be traced back to Malaysia's British common law heritage and Indonesia's in Dutch French civil law.

Two purely financial variables are included in the model, both of which were obtained from Bloomberg. CMC is the joint annual current market capitalization in Canadian dollars of two countries on a monthly average basis from year 2002 to 2007. Volume is their joint total trading volume. Both of these mass variables enter the empirical model as the product of the levels for the corresponding countries. Table 4 reports these numbers. The larger the joint market capitalization, the more highly correlated the stock markets are expected to be because market capitalization is a proxy for the level of advancement of the economies. But somewhat ambiguously, a financial market being active individually with respect to trading volume means that there may be enough variety at home that investors needn't need to look elsewhere (despite being rational to do so), resulting in a home bias; so we expect that joint volume is negatively related to the stock market correlations.

### 3.2 Extended gravity model

A different version of the base model, shown in (2), is also considered.

$$
\begin{align*}
\rho_{i j t}= & \beta_{0}+\beta_{1} O L O H+\beta_{2} \ln \left(C M C_{i t} \cdot C M C_{j t}\right)+\beta_{3} \ln \left(\text { Volume }_{i t} \cdot \text { Volume }_{j t}\right) \\
& +\beta_{4} \frac{P I_{i}}{P I_{j}}+\beta_{5} \text { Legal }_{i j}+\beta_{6} \frac{E F I_{i t}}{E F I_{j t}}+\varepsilon_{i j t}  \tag{2}\\
P I_{i}> & P I_{j}, E F I_{i t}>E F I_{j t}
\end{align*}
$$

The physical measures of distance, $G C D$, and a common border are replaced by a financial measure of distance, overlapping (stock market) opening hours, OLOH. Cities that are far from one another may still be in the same time zone and therefore have largely overlapping trading hours; OLOH captures the fact that their financial distance may be small in this respect. Markets with overlapping opening hours may react synchronously to global events, implying a tighter co-movement of their markets' returns. Data on overlapping stock market opening hours were collected from the websites of the individual exchanges (see Table 5) and trading hours in local and Hong Kong time are summarized in Table 6 below. The United States, Canada, Mexico, Chile and Peru overlap considerably, while Australia and New Zealand overlap the most.
Table 5-Overlapping opening hours
The figure indicators how many overlapping trading hours there are between two countries' stock exchange.

Table 6-Trading hours

| Country | Exchange | Trading Hours <br> (Mon to Fri) <br> (Local Time) | Trading Hours <br> (Mon to Fri) <br> (Hong Kong Time) |
| :---: | :---: | :---: | :---: |
| US | AMEX, Nasdaq, NYSE | $9: 30-16: 00(6.5 \mathrm{hrs})$ | $22: 30-5: 00$ |
| Japan | Tokyo Stock Exchange | $9: 00-11: 00,12: 30-15: 00(4.5 \mathrm{hrs})$ | $8: 00-10: 00,11: 30-14: 00$ |

| Chile | Santiago Stock Exchange | $9: 30-16: 30(7 \mathrm{hrs})$ | $21: 30-5: 30$ |
| Peru | Lima Stock Exchange | $9: 30-16: 00(6.5 \mathrm{hrs})$ | $22: 30-5: 00$ |

Source: Each country's stock market website
$P I$ is the pluralism index of a country, a measure of its religious diversity. The pluralism index, calculated according to World Christian Encyclopedia 1982, is one minus the Herfindahl index of adherents in 2000 to nine major religions, among persons expressing adherence to some religion. The religions are Buddhism, Catholicism, Hinduism, Islam, Judaism, Protestantism, Orthodox, other eastern religions, and a catch-all. These data are from Barrett (1982). I grouped data on religious adherence into the above nine categories. The Herfindahl index in this case is the sum of the squares of the fraction of the population belonging to each religion, and therefore a high pluralism index value is indicative of greater religious diversity, and can be interpreted as the probability that any two randomly selected persons in a country do not belong to the same religion. A pluralistic society is one in which numerous distinct ethnic, religious, or cultural groups coex-
ist amiably. People from different countries may have cultural ties from their religions, which influences their economic and financial behaviour. My empirical model uses the ratio of pluralism indexes of two countries, effectively making it an odds ratio of the diversity of one country to another; for example, an observed pluralism index ratio of 3 would suggest that one country is three times as likely as the other to be diverse in the sense implied by the calculation of the Herfindahl index. I hypothesize that the stock markets of countries that are more pluralistic will be more highly correlated with those that are less so because the diversity of the former increases the likelihood of religious ties to those in the latter.

EFI is a country's economic freedom index as compiled by the Heritage Foundation for the years 2002 to 2007 . The index is a grade from 0 to 100 assigned to each country from scores assessed for freedom enjoyed by or pertaining to business, trade, fiscal matters, investment, finance, labour, size of government, monetary policy, property rights, and freedom from corruption, all weighted equally. In 2007, Hong Kong maintained its status as the world's freest economy, a position it has held for more than 10 consecutive years. It was the only economy to score more than 90 on the 100-point economic freedom scale. Singapore remains close, ranked as the world's second freest economy. Carlsson and Lundstrom (2002) found that GDP growth bears a positive and robust relationship to a number of index variables, notably, legal structure, private ownership, and freedom to use an alternative currency in commerce. As with the pluralism index, I use the ratio of two countries' economic freedom indexes as a measure of their difference in economic freedom. A country that enjoys greater economic freedom is more open and attractive to foreign investors and thus suggests higher correlations with other countries. I therefore hypothesize an inverse relationship between the discrepancy in economic freedom and the correlation between markets. The pluralism and economic freedom indices are summarized in Table 7.

Table 7 - Pluralism and economic freedom indices

| Country | Pluralism Index | Economic Freedom Index |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 2007 | 2006 | 2005 | 2004 | 2003 | 2002 | Average |
| Australia | 0.51 | 81.0 | 79.4 | 78.5 | 77.9 | 77.4 | 77.3 | 78.6 |
| Canada | 0.56 | 78.1 | 77.5 | 75.8 | 75.3 | 74.8 | 74.6 | 76.0 |
| Chile | 0.22 | 79.0 | 79.3 | 79.1 | 76.9 | 76.0 | 77.8 | 78.0 |

### 3.3 An alternative version of the extended gravity model

The model in (3) below replaces legal origin and economic freedom with a security law index, SLI, proposed by La Porta et al (2006), to create a more parsimonious version of the model in (2).

$$
\begin{align*}
\rho_{i j t}= & \beta_{0}+\beta_{1} O L O H+\beta_{2} \ln \left(C M C_{i t} \cdot C M C_{j t}\right)+\beta_{3} \ln \left(\text { Volume }_{i t} \cdot \text { Volume }_{j t}\right) \\
& +\beta_{4} \frac{P I_{i}}{P I_{j}}+\beta_{5} \frac{S L I_{i}}{S L I_{j}}+\varepsilon_{i j t}  \tag{3}\\
P I_{i} & >P I_{j}, S L I_{i}>S L I_{j}
\end{align*}
$$

The security law index covers disclosure requirements, liability standards, and public enforcement, which itself encompasses liability standards, supervisor characteristics, rule making powers, investigative powers, orders and criminal sanctions. The data was obtained from Table II of La Porta et al (2006) and the index is computed as the average of the above three areas. Table 8 provides the details.

Table 8-Security law index

| Country | Disclosure <br> Requirements | Liability <br> Standard | Public <br> Enforcement | Security Law Index |
| :---: | :---: | :---: | :---: | :---: |
| USA | 1 | 1 | 0.9 | 0.97 |
| Japan | 0.75 | 0.66 | 0 | 0.47 |
| Hong Kong | 0.92 | 0.66 | 0.87 | 0.82 |
| China | 0.33 | 0 | 0.33 | 0.22 |
| Taiwan | 0.75 | 0.66 | 0.52 | 0.64 |
| Singapore | 1 | 0.66 | 0.87 | 0.84 |
| Thailand | 0.92 | 0.22 | 0.72 | 0.62 |
| Philippines | 0.83 | 1 | 0.83 | 0.89 |
| South Korea | 0.75 | 0.66 | 0.25 | 0.55 |
| Australia | 0.75 | 0.66 | 0.9 | 0.77 |
| New Zealand | 0.67 | 0.44 | 0.33 | 0.48 |
| Indonesia | 0.5 | 0.66 | 0.62 | 0.59 |
| Malaysia | 0.92 | 0.66 | 0.77 | 0.78 |
| Russia | 0 | 0.11 | 0.57 | 0.23 |
| Canada | 0.92 | 1 | 0.8 | 0.91 |
| Mexico | 0.58 | 0.11 | 0.35 | 0.35 |
| Chile | 0.58 | 0.33 | 0.6 | 0.50 |
| Peru | 0.33 | 0.66 | 0.78 | 0.59 |

The table classifies countries showing the securities law variables for each country covering the equal weighting area of (1)disclosure requirements,(2) Liability standard, (3) Public enforcement

The security law index may subsume economic freedom and legal origin. The law regulates the stock market and measures the development of the stock market, including market openness and other relevant characteristics. The security law index, like economic freedom, is applied here as the ratio of the indexes of two countries, so it measures the discrepancy in security law between two countries. A higher security law index will lead to a higher-level development of stock market and thus increases the correlations with other stock markets. So we hypothesize an inverse relationship between the discrepancy in security law and the correlation between markets.

### 3.4 Summary of hypotheses

Nine hypotheses were posed in this section: (1) Greater similarity in financial behavior, which in turn implies more highly correlated stock markets. (2) Countries with a common border or strait are expected to have more highly correlated stock markets. (3) Stock markets of countries whose current legal systems have the same origin will be more highly correlated. (4) Larger markets are more highly correlated. (5) Active markets are less correlated. (6) The more that trading hours overlap, the higher the correlation between markets. (7) The greater the discrepancy in religious pluralism, the higher the correlation between stock markets. (8) The greater the discrepancy in economic freedom, the lower the correlation between stock markets. (9) The greater the discrepancy in security law, the lower the correlation between stock markets.

## 4. Results and discussion

Regression results for the base gravity model and the two extended gravity models is reported in this part, followed by a discussion of how the results are relevant to the home bias anomaly and the liberalization of China's stock market. Throughout the discussion,
reference is made to specific examples of stock market correlation coefficients. These numbers are reported in the appendix for each year of the sample.

### 4.1 Base gravity model

The results for the base gravity model, which includes the geographical distance variables, is presented in Table 9.

Table 9-Ordinary Least Squares Estimation of the Base Gravity Model

|  | Variable | Coefficient | $t$-statistic |
| :---: | :---: | :---: | :---: |
| $\beta_{0}$ | Intercept | 0.39772 | $1.72^{*}$ |
| $\beta_{1}$ | Great circle distance | 0.01060 | 0.83 |
| $\beta_{2}$ | Common border | 0.07322 | $2.04^{* *}$ |
| $\beta_{3}$ | Joint market capitalization | 0.02906 | $6.72^{* * *}$ |
| $\beta_{4}$ | Joint volume | -0.01746 | $-4.05^{* * *}$ |
| $\beta_{5}$ | Legal origin | 0.07848 | $3.69^{* * *}$ |
| $\mathrm{~N}=918$, Adjusted R -square $=0.0748$ |  |  |  |

Geographical distance, as measured by the great circle distance, is not statistically significant, but having a common border is, and it is associated with a seven percentage point increase in the correlation of market returns. The size variable, represented by the product of current market capitalizations, is positive and statistically significant at $99 \%$. The larger the market, the more correlated it is with other markets. Larger markets tend to be are more diversified across industrial sectors and thus co-move more closely in response to common or global events. This result is consistent with Flavin, Hurley, and Rousseou (2002) and Huang (2006). In 2002, the highest correlation is between the US and Australia, whose joint market capitalization is much bigger than that of the US and Indonesia whose correlation is -0.0164 . The CMC of Australia is ten times larger than the CMC of Indonesia. But the product of trading volume, an indicator of joint market activeness, is statistically significant at $99 \%$ confidence level with a negative sign. The
more active one market is, the less it need turn to or be concerned with other markets; in other words, I interpret an active market is more independent, all things being equal. From 2002 to 2007, China and Japan are two typical countries with relatively higher trading volumes, but their correlation with other markets are very low. In 2006, China's trading volume was as high as 1.2 trillion and ranked first among all countries, but its average correlation of 0.1179 with other countries is the lowest of all. As stated before, an active market may mean that there is enough variety and enough going on at home that people from that country don't need to look elsewhere for investments, resulting in a home bias. This assumes selective attention and informational asymmetries and thus leads to a lower correlation with other markets.

Sharing a common legal heritage is significantly related to the correlation between markets, enough so to be associated with a correlation that is eight percentage points higher on average. In my sample, eight countries have an English common law heritage, and their markets have higher correlations with each other, but lower correlations with German civil law origin countries. In 2002, the US and Australia, which have the same legal origin, had a correlation as 0.8769 , whereas the US and Japan, whose legal origins differ, had a correlation of 0.2883 . La Porta et al (1997) examined the influence of legal rules on capital markets across 49 countries and found strong evidence that countries with different legal origins provide different rights and protection of their investors. Levine (2005) found that, at a broader lever, there is some evidence that legal systems that embrace jurisprudence have better property rights and, in turn, better financial systems.

### 4.2 Extended gravity model

Ordinary least squares estimates for the extended model in (2) are reported in Table 10.

Table 10-Ordinary Least Squares Estimation of the Extended Gravity Model

|  | Variable | Coefficient | $t$-statistic |
| :---: | :---: | :---: | :---: |
| $\beta_{0}$ | Intercept | 0.49504 | $2.44^{*}$ |
| $\beta_{1}$ | Overlapping opening hours | 0.01292 | $2.69^{* * *}$ |
| $\beta_{2}$ | Joint market capitalization | 0.02565 | $5.96^{* * *}$ |
| $\beta_{3}$ | Joint volume | -0.01371 | $-3.22^{* * *}$ |
| $\beta_{4}$ | Pluralism | 0.01090 | $3.33^{* * *}$ |
| $\beta_{5}$ | Legal origin | 0.08007 | $3.75^{* * *}$ |
| $\beta_{6}$ | Economic freedom | -0.12163 | $-2.28^{* *}$ |

$\mathrm{N}=918$, Adjusted R-square $=0.1071$

All variables are significant and of the predicted sign; and notably, the magnitude of those carried over from the base model, joint volume, joint market capitalization and legal origin, are unaffected in the presence of the new variables, overlapping operating hours, pluralism, and economic freedom.

Overlapping operating hours is associated with a significant, although modest, heightened correlation, consistent with fewer informational asymmetries. The religious diversity variable, applied by quotient of pluralism index of two countries, is statistically significant at $99 \%$ confidence level with a positive sign. The larger the distance between pluralism indexes of two countries, the more correlated their markets. This is not intuitive. Suppose the world has five religions, A, B, C, D, and E. The most plural country, I, is represented by all of them. There is a country, II, of median pluralism which has two religions, C and E . There are also two mono-religion countries, III and IV, one with A and the other with C. Country I, which is the most plural country, has religious ties with all the other countries, but country II only has religious ties with country I and IV. Comparatively speaking, a more plural country has more cultural ties with other countries than a less plural one, thus the more cultural ties indirectly increase the financial market correlations. Claims that religion affects economic and financial behaviors can be found in Hun-
tington (1996), Landes (1999), and Inglehart and Baker (2000) who argued that explanations for economic growth should go further to incorporate cultural factors. Religion is an important aspect of culture and Barro and McCleary (2003) who found that pluralism indirectly but significantly affected economic growth. They found that greater religious pluralism was associated with higher church attendance and stronger religious belief. For given church attendance, stronger adherence to some beliefs, notably in Heaven, Hell, and an after-life-were associated with higher economic growth.

Economic freedom, like pluralism, is applied here as the ratio of the indexes of two countries, so it measures the discrepancy in freedom. Here the result is opposite to that of pluralism, where the coefficient has a negative sign: the bigger the discrepancy in economic freedom, the lower the correlation of the two markets. And that coefficient is the largest: -0.12. Marshall (2005) reviewed previous research on the relationship between economic freedom and equity markets and found that cross-country equity returns were directly related to increases in economic freedom. For investors seeking superior investment returns, countries likely to experience an increase in economic freedom should be selected for investment. The countries with higher economic freedom like Hong Kong and Singapore are more open and attractive to foreign investors and thus lead to a positive impact on market correlation. In contrast, countries with lower economic freedom like Russia are not open and less attractive to foreign investors. The correlation of Hong Kong and Singapore in 2003 is 0.6499 , while the correlation of Hong Kong and Russia is 0.1181. The economic freedom index of Hong Kong and Singapore is very close, so the discrepancy is much smaller than that of Hong Kong and Russia.

### 4.3 Alternative extended gravity model

Ordinary least squares estimates for the extended model using security law index in (3) to
replace legal origin and economic freedom is reported in Table 11. All of the independent variables are significant as before.

Table 11-Ordinary least squares estimates for the alternative extended model using Security law index

|  | Variable | Coefficient | $t$-statistic |
| :---: | :---: | :---: | :---: |
| $\beta_{0}$ | Intercept | 0.53089 | $2.99^{* * *}$ |
| $\beta_{1}$ | Overlapping opening hours | 0.01227 | $2.58^{* *}$ |
| $\beta_{2}$ | Joint market capitalization | 0.02684 | $6.36^{* * *}$ |
| $\beta_{3}$ | Joint volume | -0.01516 | $-3.66^{* * *}$ |
| $\beta_{4}$ | Pluralism | 0.01054 | $3.31^{* * *}$ |
| $\beta_{5}$ | Security law index | -0.06821 | $-6.09^{* * *}$ |

$\mathrm{N}=918$, adjusted R-square $=0.1071$
Here the result of security law index is the same as economic freedom, where the coefficient has a negative sign: the bigger the discrepancy in security law, the lower the correlation of the two markets. Similarity in the security law system is associated with higher financial market correlations and discrepancy in the security law system associated with lower correlations. La Porta et. al (2006) showed that security laws, especially laws mandating disclosure and facilitating private enforcement through liability rules, benefit the development of stock markets. A higher security law index will accompany if not lead to higher-level development of a stock market and thus increase the correlation with like markets. When one market is poorly protected, there is indicative of market segmentation as Bartram and Dufey (2001) market segmentation is "caused by barriers that are difficult for the investors to overcome, such as legal restrictions on international investment, thus the correlation with the other markets is low. The issue of stock market openness will be especially addressed in the next section.

### 4.4 Robustness to a measure of economic development

It can be argued that the variables studied might lose their significance in the presence of fundamental economic variables that gauge similarities in the level of economic development or the prosperity of the countries considered. The question of which fundamentals are most appropriate to include is beyond the scope of this study. However, to provide a non-rigorous sense of the robustness of the results, I include, somewhat arbitrarily, the rate of Internet penetration as a measure of the level of economic advancement of the countries. This rate, obtained from the International Telecommunication Union, corresponds to the percentage of the total population of a given country or region that uses the Internet. Table 12 reports the details, and shows that penetration rates have been increasing over time, and that there is variation between countries.

Table 12-Internet penetration rate (\%)

|  | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| US | 59.63 | 62.61 | 65.73 | 69 | 70 | 72.5 |
| Japan | 46.44 | 48.26 | 62.13 | 66.59 | 68.27 | 68.85 |
| Hong Kong | 42.9 | 46.67 | 49.98 | 50.08 | 52.97 | 54.97 |

Source : www.itu.int

The model in (3) is re-estimated with the ratio of Internet penetration rates between countries and the results reported in Table 13. All of the original independent variables remain significant as before and the R-squared is increased by approximately two percentage points.

Table 13-Ordinary least squares estimates for the alternative extended model using Security law index and Internet penetration rate

|  | Variable | Coefficient | $t$-statistic |
| :---: | :---: | :---: | :---: |
| $\beta_{0}$ | Intercept | 0.51097 | $2.89^{* * *}$ |
| $\beta_{1}$ | Overlapping opening hours | 0.01254 | $2.65^{* * *}$ |
| $\beta_{2}$ | Joint market capitalization | 0.02316 | $5.35^{* * *}$ |
| $\beta_{3}$ | Joint volume | -0.01230 | $-2.93^{* * *}$ |
| $\beta_{4}$ | Pluralism | 0.00969 | $3.05^{* * *}$ |
| $\beta_{5}$ | Security law index | -0.06773 | $-6.08^{* * *}$ |
| $\beta_{6}$ | Internet penetration | -0.00645 | $-3.51^{* * *}$ |
| $\mathrm{~N}=918$, adjusted R -square $=0.1238$ |  |  |  |

The interpretation of Internet penetration is the same as that for the security law index in the sense of gauging discrepancies in the level of sophistication and advancement of the economies. From Table 14, we can see US and Canada are the two countries with the highest internet penetration rates in our sample while Indonesia is the lowest. The market correlation in 2002 for the US and Canada is .83 but for the US and Indonesia it is -0.016.

### 4.5 What lies behind the home equity bias

The tendency of investors to allocate a disproportionate share of their wealth to domestic securities or, more often, to ignore foreign securities entirely, is in violation of the principles of portfolio theory and theories of market equilibrium such as the Capital Asset Pricing Model, and has been studied for some time. This study suggests that the variables that are associated with the correlation of stock markets bear some relevance to home bias, namely that those countries that display low correlations with others also tend to have the biggest home bias. It is natural to suggest that investors simply shy away from companies with which they are presumably unfamiliar, particularly those domiciled in countries with unfamiliar laws and cultures. Distance, in every sense of the word, would seem to matter in portfolio selection and thus be an essential part of the study of financial market segmentation and integration. Lewis (1999), Srong and Xu (2003), and Karolyi and Stulz (2003), among others, explain that the bias can be explained by explicit barriers to international investments, which were regulations, costs, information asymmetry, insider benefits, hedging motives and behavioral traits. But globalization has removed many barriers to international investment, especially in developed markets. Information too is more widely available and rapidly disseminated, especially for the multi-national firms that make up the much of world market capitalization. Interest has therefore turned to behavioural explanations for the persistence of the bias.

Given that gravity models make use of what might be considered behavioral variables, there is an opportunity to see whether the countries that display the strongest home bias are also the ones whose stock markets are least correlated with those of others, which in turn may be explained by gravity model variables. Data from the International Monetary Fund's Coordinated Investment Portfolio Survey (CIPS) is used here to calibrate a home bias ratio for each country along the lines of Solnik (2005). CIPS provides
detailed statistics on the geographical breakdown of investment and foreign equity holdings for each country at the end of 2007. All the 18 countries are covered in IMF's statistics. The ratio of foreign to world market capitalization and foreign holdings within equity portfolios is computed in Table 12. According to Kho and Warnock (2006), the home bias ratio (HBR) is one minus the ratio of the weights of foreign stocks in the investors' portfolio and in the world portfolio as in (4):

$$
\begin{equation*}
H B R=1-\frac{\alpha / w}{m_{i} / W} \tag{4}
\end{equation*}
$$

Here, $\alpha$ refers to the holdings of international stocks by domestic investors and $w$ indicates domestic equity holdings. $m_{i}$ refers to the domestic market capital and W indicates total world market capital. This ratio is zero if there is no home bias and one if no foreign assets are owned (complete home bias). Table 14 and Figure 3 report the variables.
Table 14— Foreign and domestic holdings of equity

|  | Holdings of international stocks by domestic investors | Holdings of domesic stocks by international investors | Domestic market cap. | International market cap. | Domestic equity holdings | International equity holdings | Foreign Market Cap. | Foreign Holdings | Home bias Ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Notation | alpha | beta | m | $\mathrm{m}_{\mathrm{i}}$ | w | $\mathrm{w}_{\mathrm{i}}$ | $\mathrm{m}_{/} / \mathrm{W}$ | alpha/w | $1-\left(m_{i} / W\right) /$ (alpha/w) |
| US | 5,247,983 | 2,889,037 | 19,922,280 | 40,952,119 | 22,281,226 | 38,593,173 | 67.3\% | 23.6\% | 65.0\% |
| Japan | 573,469 | 1,040,927 | 4,663,778 | 56,210,621 | 4,196,320 | 56,678,079 | 92.3\% | 13.7\% | 85.2\% |
| Hong Kong | 518,717 | 326,384 | 2,654,416 | 58,219,983 | 2,846,749 | 58,027,650 | 95.6\% | 18.2\% | 80.9\% |
| China | 0 | 387,920 | 4,478,867 | 56,395,532 | 4,090,947 | 56,783,452 | 92.6\% | 0.0\% | 100.0\% |
| Taiwan | 0 | 153,761 | 663,716 | 60,210,683 | 509,955 | 60,364,444 | 98.9\% | 0.0\% | 100.0\% |
| Singapore | 140,553 | 127,920 | 539,177 | 60,335,222 | 551,810 | 60,322,589 | 99.1\% | 25.5\% | 74.3\% |
| Thailand | 3,237 | 46,611 | 197,129 | 60,677,270 | 153,755 | 60,720,644 | 99.7\% | 2.1\% | 97.9\% |
| Philippines | 186 | 18,908 | 103,007 | 60,771,392 | 84,285 | 60,790,114 | 99.8\% | 0.2\% | 99.8\% |
| Korea | 106,110 | 257,405 | 1,122,606 | 59,751,793 | 971,311 | 59,903,088 | 98.2\% | 10.9\% | 88.9\% |
| Australia | 262,081 | 301,646 | 1,298,315 | 59,576,084 | 1,258,750 | 59,615,649 | 97.9\% | 20.8\% | 78.7\% |
| New Zealand | 27,411 | 11,641 | 47,486 | 60,826,913 | 63,256 | 60,811,143 | 99.9\% | 43.3\% | 56.6\% |
| Indonesia | 511 | 38,989 | 211,693 | 60,662,706 | 173,215 | 60,701,184 | 99.7\% | 0.3\% | 99.7\% |
| Malaysia | 9,422 | 53,496 | 325,290 | 60,549,109 | 281,216 | 60,593,183 | 99.5\% | 3.4\% | 96.6\% |
| Russia | 4,081 | 182,113 | 995,000 | 59,879,399 | 816,968 | 60,057,431 | 98.4\% | 0.5\% | 99.5\% |
| Canada | 563,661 | 465,155 | 2,186,550 | 58,687,849 | 2,285,056 | 58,589,343 | 96.4\% | 24.7\% | 74.4\% |
| Mexico | 3,672 | 120,981 | 397,725 | 60,476,674 | 280,416 | 60,593,983 | 99.3\% | 1.3\% | 98.7\% |
| Chile | 65,057 | 11,747 | 212,910 | 60,661,489 | 266,220 | 60,608,179 | 99.7\% | 24.4\% | 75.5\% |
| Peru | 0 | 3,281 | 69,386 | 60,805,013 | 66,105 | 60,808,294 | 99.9\% | 0.0\% | 100.0\% |
| World market cap. (W) | 60,874,399 |  |  |  |  |  |  |  |  |

Figure 3-Home bias Ratio

A value less than US $\$ 500,000$ is indicated as a zero value. Holdings of international stocks by domestic investors and holdings of domestic stocks by international investors are obtained from CIPS of IMF. Domestic market cap and world market cap are obtained from The World Federation of Exchanges.

The home bias ratio for New Zealand and US at the end of 2007 is $56.6 \%$ and $65.0 \%$ respectively. Compared with that of other countries, equity home bias is not prevalent in these two developed countries. But investors from all the other countries exhibit a large degree of home bias (greater than 70\%). Home bias is extreme in the emerging markets where the bias ratio is exceeds $95 \%$, except for Chile which is $75.5 \%$.

Our gravity model shows the developed markets are those markets with large size, free and advanced economies, so the correlation is higher between each other, while the emerging markets are the opposite. This is consistent with the home bias ratio results.

### 4.6 Stock market openness and correlation: the case of China

Opening stock markets to foreign portfolio investment is a key step in world market inte-
gration, which is beneficial for the developing economy. All of the developing countries in the sample have undergone official liberalization or cross-listing or country fund listing since the late 1980s (Table 15). Data of Official liberalization events (I), cross-listing or country fund listing events (II), and deliberalization events (III) is given by Bae et al. (2006) and Bekaert et al. (2002).

Table 15-Schedule of liberalization of stock markets

| Country | Official <br> liberalization | Cross-listing or <br> country fund <br> listing | De-liberalization |
| :---: | :---: | :---: | :---: |
| Chile | $01 / 1992$ | - | $07 / 1995$ |
| China | $03 / 2003$ | $03 / 1997$ | - |
| Indonesia | - | $10 / 1994$ | - |
| Korea | $01 / 1992$ | $10 / 1994$ | - |
| Malaysia | $12 / 1988$ | $02 / 1990$ | $02 / 1994$ |
| Mexico | $05 / 1989$ | - | $05 / 1990$ |
| Peru | - | $09 / 1994$ | - |
| Philippines | $06 / 1991$ | $10 / 1994$ | - |
| Russia | - | $11 / 1996$ | $05 / 1997$ |
| Taiwan | $01 / 1991$ | $04 / 1995$ | - |
| Thailand | $09 / 1987$ | - | $06 / 1997$ |

Consider the case of China, whose official liberalization took place between 2002 and 2007. This allows us to examine the associations between stock market openness and correlation. The reform of the Chinese financial system continued from 1997 to 2007. In March 2003, investment quota for the QFII Scheme was started to allocate to qualified financial institutions. A capital injection of 45 billion USD into the Bank of China and China Construction Bank was announced in an effort to recapitalize the banks. This reform was the key standard that the Chinese stock market is officially liberalized. In the year of 2006, Qualified Domestic Institutional Investors (QDII) Scheme was introduced. It refined the interbank money market and introduced flexibility to the exchange rate sys-
tems. Whether the degree of market openness has something to do with market correlation is an important question of this study. We can refer to Appendix for details. In the year 2002, except for Hong Kong and Malaysia, China has a negatively low correlation with all other markets with average correlation of -0.1975 , while in the year of 2004, after its official liberalization, China has a positive correlation with almost all other markets with aver-age correlation of 0.2311 . In the year of 2007, after the introduction of QDII Scheme, its average market correlation is increased to 0.2905 . Clearly, liberalization and other acts of opening to foreign equity investors have a positive impact on stock market correlation, so the market openness indicator should act as an important factor included in the gravity model in this paper.

## 5. Conclusion

Gravity factors have long been used to explain economic correlations between goods markets. Our analysis shows that the gravity model with extended attraction factors is also applicable to the regional financial asset market. The alternative home bias measure--overlapping opening hours may be acting as a proxy for information asymmetries in a regional study. We also find market size, legal origin influence cross-country correlation which is consistent with former empirical studies. The new introduction of market activeness factor--trading volume and the extended unphysical distance variables such as religious diversity, economic freedom, security law index play an important role too. The robustness test introduces the internet penetration rate, which is also robust in the crosscountry correlation.
